## Abstract

Prediction, tracking, and retrodiction for targets whose motion is constrained by external conditions (e.g., shipping lanes, roads) present many challenges to tracking systems. The targets are moving along a path, defined by way-points and segments. Measurements are obtained by sensors at low revisit rates (e.g., spaceborne). Existing tracking algorithms assume that the targets follow the same motion model between successive measurements, but in a low revisit rate scenario targets may change the motion model between successive measurements. A prediction algorithm is proposed here, which addresses this issue by considering possible motion model whenever targets move to a different segment. Further, when a target approaches a junction, it has the possibility to travel into one of the multiple segments connected to that junction. To predict the probable locations, multiple hypotheses for segments are introduced and a probability is calculated for each segment hypothesis. When measurements become available, segment hypothesis probability is updated based on a combined mode likelihood and a sequential probability ratio test is carried out to reject the hypotheses with low probability. Retrodiction for path constrained targets is also considered, because in some scenarios it is desirable to find out the target's exact location at some previous time (e.g., at the time of an oil leakage). A retrodiction algorithm is developed for path constrained targets so as to facilitate motion forensic analysis. Simulation results are presented to validate the proposed algorithms.

KEYWORDS: prediction, target tracking, retrodiction, path-constrained targets, segment hypothesis

# Acknowledgements

The successful completion of my research presented in this thesis could not have been accomplished without the help and support of a number of people. I am glad to have the opportunity to acknowledge them here.

First and foremost, I would like to express my deepest gratitude to my academic supervisor, Dr. T. Kirubarajan whose expert advice and guidance, motivated me achieve excellence in my work. I would like to thank him for his valuable inputs throughout the course of my research.

I am most grateful to Dr. Tharmarasa, for his good advice and support. His thorough reviews and perceptive comments greatly improved the quality of my thesis work. I would also like to thank Dr. Alexandru Patriciu and Dr. Steve Hranilovic for being members of my thesis defense committee. I appreciate all the time the members of my committee took to read this thesis and for providing their input and thoughts on the subject.

I am thankful to the Department of Electrical & Computer Engineering, for providing me an opportunity to pursue my research at McMaster University. I would also like to thank Cheryl Gies of the Department of Electrical & Computer Engineering for providing me with prompt administrative support.

Last, but by no means least, I would like to thank my parents, aunty, sisters and

their families for their their unequivocal support throughout, as always, for which my mere expression of thanks likewise does not suffice.

# Chapter 1

# Introduction and Problem Statement

The targets are moving along a constrained path with varying terrain conditions. The terrain conditions can affect the movement of targets in direction, velocity and maneuvering. The path is defined by way-points and segments (Kirubarajan *et al.*, 2000). Further, a path can branch, merge or cross. Because of the varying terrain and path constraints, target trajectory can evolve according to one of the multiple motion modes available. It is evident that a multiple model approach is required to handle all possible motion modes and path constraints.

### **1.0.1** Prediction and Tracking

Fixed structure Interacting Multiple Model (IMM) estimator (Blom and Bar-Shalom, 1988) consists of models to handle all possible motion modes and path constraints can be a solution to handle all possible motion modes. But due to the "competition"

among the models (Li and Bar-Shalom, 1996), fixed structure IMM results in a degraded estimates. This issue is overcome by Variable Structure Interacting Multiple Model (VS-IMM) filter, which adaptively modifies the filter modules based on terrain topography. It is a modified version of IMM where models in a mode set can vary based on constraints. Since the mode set is adjusted based on the path map information available, VS-IMM estimator outperforms typical IMM estimator (Kirubarajan et al., 2000) and the effectiveness of VS-IMM for path constrained targets has been shown in (Kirubarajan et al., 2000), (Pannetier et al., 2005) and (Shea et al., 2000). In (Streller, 2008), Variable Structure Multiple Model (VS-MM) estimator, another version of multiple model approach, which does not use interaction like VS-IMM, is used to track ground targets effectively. By avoiding interaction between the multiple models, VS-MM avoids the bad estimations given by VS-IMM at junctions (Streller, 2008). Particle filter approach is also widely used for ground targets with path maps and has shown better performances in (Arulampalam et al., 2002), (Kyriakides et al., 2008) and (Ulmke and Koch, 2006). But due to the large computation time associated with the particle filter, Kalman filter approaches (IMM, VS-MM, VS-IMM) are widely used for the path constrained targets (Streller, 2008).

Since the targets are constrained to path, prediction should be along the path with the available prior information (e.g., path map, target class, destination). Existing algorithms, except (Pannetier *et al.*, 2005), do not consider path map information in prediction stage, which results in predicted target state in an off-path position. In (Pannetier *et al.*, 2005), a projection mechanism is used to constrain the target state to be on path. In this thesis, a different approach is used to keep the predicted state along the path rather than the estimate. Further when a target moves towards a junction, the path on which the target may travel is unknown. In (Kirubarajan *et al.*, 2000) and (Shea *et al.*, 2000), uncertainty at junctions is handled by temporarily augmenting the mode set to accommodate all possible modes, which represent the target motion along the possible segments. In this approach, the segment followed by the target is not considered. In this thesis junctions are handled by multiple hypotheses for segments (Pannetier *et al.*, 2005). Segment hypotheses keep all the possible path sequences a target can travel and when the measurements are received, a sequential probability ratio test is carried out to select the best hypothesis and reject all other hypotheses. In addition, magnitude of target velocity may vary based on the path segment. Existing algorithms do not have the mechanism to incorporate this prior information. A prediction algorithm is proposed in this thesis which follows a multi-step prediction technique and incorporates the magnitude and direction of target velocity constrained to path segment.

#### 1.0.2 Retrodiction

Smoothing or retrodiction is the estimation of the state at a time within the data time interval (Bar-Shalom *et al.*, 2001). With a certain time delay and some additional computational load, the estimate at a given time can be improved significantly. Retrodiction can be used for performance evaluation for real time filters and motion forensic analysis where small time delay is permitted. Various methods have been proposed for retrodiction in literature. Fixed interval smoothing, delaying certain amount of time to get a better estimate, for Markovian switching systems is developed in (Helmick *et al.*, 1995). Two multiple model filters, where one of the filters propagates in the forward-time direction and the other one propagates in the backward-time direction is used in the above smoothing algorithm. This is similar to the Fraser-Potter (Fraser and Potter, 1969) adopted for single model smoothing algorithm. In (Koch, 2000), a fixed interval smoothing to IMM-MHT applications is given based on standard Rauch-Tung-Striebel (RTS) smoothing (Rauch *et al.*, 1965). Fixed lag smoothing uses the past and present data to compute the state estimate certain time step behind the present time. In (Helmick *et al.*, 1994), two different approaches for one step fixed lag smoothing algorithms are given where the methods differ by the sampling period upon which the state of the system is conditioned. An augmented approach, applying the basic IMM approach to a state augmented system, for fixed lag IMM smoothing is given in (Tugnait, 2000). But no algorithms have been specifically developed for path constrained problems in literature. In this thesis a retrodiction algorithm is presented for variable structure IMM based on (Koch, 2000) and then it is extended to path constrained targets.

### **1.1** Estimator for Target Tracking

Due to the large computation time associated with the particle filter method, Kalman filter approaches are widely used for path constrained target tracking applications (Streller, 2008). Subsection 1.1.1 contains the equations for a Kalman filter and subsection 1.1.2 presents the equations for IMM filter, which are important for a better understanding of this thesis.

### 1.1.1 Kalman Filter

The target evolution state  $\mathbf{x}(k)$ , which was defined in (Bar-Shalom *et al.*, 2001), can be written as

$$\mathbf{x}(k) = F(k, k-1)\mathbf{x}(k-1) + \Gamma(k, k-1)\upsilon(k-1)$$
(1.1)

where F(k, k-1) is the state transition matrix and  $\Gamma(k, k-1)$  is the vector gain. v(k-1) is the white Gaussian process noise sequence with covariance given by Q(k, k-1). Target originated measurement can be written as

$$\mathbf{z}(k) = H(k)\mathbf{x}(k) + w(k) \tag{1.2}$$

where H(k) is the observation matrix. The white Gaussian measurement noise sequence w(k) is independent of v(k) and its covariance is  $\Sigma(k)$ .

The predicted state  $\hat{x}(k|k-1)$  at time k is

$$\hat{x}(k|k-1) = F(k,k-1)\hat{x}(k-1|k-1)$$
(1.3)

and the associated predicted state covariance P(k|k-1) is

$$P(k|k-1) = F(k,k-1)P(k-1|k-1)F(k,k-1)' + \Gamma(k,k-1)Q(k,k-1)\Gamma(k,k-1)^{T}$$
(1.4)

where  $\hat{x}(k-1|k-1)$  is the state estimate and P(k-1|k-1) is the associated covariance

at time (k-1). The predicted measurement  $\hat{z}(k|k-1)$  at time k is

$$\hat{z}(k|k-1) = H(k)\hat{x}(k|k-1)$$
(1.5)

and the associated innovation covariance is

$$S(k) = H(k)P(k|k-1)H(k)' + R(k)$$
(1.6)

The state estimate update at time k is

$$\hat{x}(k-1|k-1) = \hat{x}(k|k-1) + W(k)v(k)$$
(1.7)

where W(k) is the filter gain given as

$$W(k) = P(k|k-1)H(k)'S(k)^{-1}$$
(1.8)

and innovation is given by

$$v(k) = z(k) - \hat{z}(k|k-1)$$
(1.9)

The covariance matrix associated with  $\hat{x}(k-1|k-1)$  is given by

$$P(k) = P(k|k-1) - W(k)S(k)W(k)'$$
(1.10)

The above equations are provided here for completeness and to introduce the notions for later use.

#### 1.1.2 Interacting Multiple Model Estimator

In IMM estimator, state estimate is computed under each possible current model using available fixed filters with each filter using a different 'mixed initial condition'. For each filter, 'mixed initial condition' is calculated using the previous mode conditioned estimates. The detailed derivation for IMM estimator is given in (Blom and Bar-Shalom, 1988) and steps required to calculate the state estimate is given here.

Let  $A(k-1) = (M_1(k-1), ..., M_i(k-1), ...)$  be the mode set of the IMM estimator in the time interval (k-2, k-1] and  $A(k) = (M_1(k), ..., M_j(k), ...)$  be the mode set in the time interval (k-1, k].

#### Step 1 - Calculation of the mixing probabilities

The probability that mode  $M_i$  was in effect at (k-1) given that mode  $M_j$  is in effect at k conditioned on  $Z_1^{k-1}$  is

$$\mu_{i|j}(k-1|k-1) = P\{M_i|M_j, Z_1^{k-1}\}$$
$$= \frac{1}{C_j} P\{M_j|M_i, Z_1^{k-1}\} P\{M_i|Z_1^{k-1}\}$$
(1.11)

The above mixing probabilities can be written as

$$\mu_{i|j}(k-1|k-1) = \frac{1}{C_j} \left[ p_{ij}(S_{k-1}) \right] \mu_i(k-1) \qquad \forall i, \ \forall j \tag{1.12}$$

where the normalizing constants are given by

$$C_j = \sum_{M_i \in A(k-1)} [p_{ij}(S_{k-1})] \ \mu_i(k-1) \qquad \forall j$$
(1.13)

#### Step 2 - IMM Mixing

Mixed initial condition for the filter matched to  $M_j(k-\tau)$  is computed as

$$\hat{x}^{0j}(k-1|k-1) = \sum_{M_i \in A(k-1)} \hat{x}^i(k-1|k-1) \ \mu_{i|j}(k-1|k-1) \quad \forall j$$
(1.14)

The corresponding covariance is given by

$$P^{0j}(k-1|k-1) = \sum_{M_i \in A(k-1)} \mu_{i|j}(k-1|k-1) \left\{ \hat{x}^i(k-1|k-1) + \left[ \hat{x}^i(k-1|k-1) - \hat{x}^{0j}(k-1|k-1) \right] \right] \\ \left[ \hat{x}^i(k-1|k-1) - \hat{x}^{0j}(k-1|k-1) \right]^T \right\} \quad \forall j$$
(1.15)

#### Step 3 - Mode Matched Filtering

The estimate  $\hat{x}^{0j}(k-1|k-1)$  and covariance  $P^j(k-1|k-1)$  are used as input to the filter matched to  $M_j$ , which uses z(k) to yield  $\hat{x}^j(k|k)$  and  $\hat{P}^j(k|k)$ . The likelihood function corresponding to the above filtering processes are calculated by

$$\Lambda_j(k) = P[z(k)|M_j, Z_1^{k-1}] \qquad \forall j \tag{1.16}$$

#### Step 4 - Mode probability updating

The probability of model  $(M_j)$  being in effect during the time interval (k, k-1] given

measurement data up to k can be calculated as

$$\mu_{j}(k|k) = P\{M_{j}|Z_{1}^{k}\}$$

$$= \frac{1}{C}P[z(k)|M_{j}, Z_{1}^{k-1}] P[M_{j}|Z_{1}^{k-1}]$$

$$= \frac{1}{C}\Lambda_{j}(k) \ \mu_{j}(k|k-1)$$
(1.17)

where  $\mu_j(k|k-1)$  can be written as

$$\mu_j(k|k-1) = \sum_{M_i \in A(k-1)} [p_{ij}(S_{k-1})] \ \mu_i(k-1)$$
(1.18)

### Step 5 - State estimate and covariance combination

The final state estimate and covariance are

$$\hat{x}(k|k) = \sum_{M_j \in A(k)} \hat{x}^j(k|k) \ \mu_j(k|k)$$
(1.19)

$$P(k|k) = \sum_{M_j \in A(k)} \mu_j(k|k) \left\{ P^j(k|k) + [\hat{x}^j(k|k) - \hat{x}(k|k)] [\hat{x}^j(k|k) - \hat{x}(k|k)]^T \right\}$$
(1.20)

Figure 1.1 describes the IMM algorithm that consists of two interacting filters.

Figure 1.1: IMM estimator (one cycle).

### **1.2** Motivation and Contribution of the Thesis

This thesis addresses the problem of prediction, tracking and retrodiction of path constrained targets where measurements are obtained by sensors with low revisit rates. For example, a spaceborne sensor, with varying measurement intervals may take up to 12 hours to update a measurement related to a target. The high measurement interval time between successive measurements will cause potentially degraded performance during prediction in already existing algorithms (Kirubarajan *et al.*, 2000), (Pannetier *et al.*, 2005). Updating the mode set upon a receival of a measurement is the process carried out in the above algorithms. But in a scenario where measurements are obtained by sensors at low revisit rates, mode set may need to be updated during the measurement interval due to a change in the segment in which the target is moving. The proposed algorithm addresses this issue in prediction by considering the time at which the target moves to a different segment instead of waiting for the measurement to be received. In addition, segment hypotheses are used to handle the motion uncertainty of the path constrained targets in the intersections. Retrodiction for path constrained targets is not available in the literature and a novel retrodiction algorithm is presented in this thesis. The retrodiction algorithm considers path map information and retrodiction gain is derived considering the path constraints imposed. To evaluate the performance of the proposed algorithms, Posterior Cramer Rao lower bound (PCRLB) for path constrained targets is given.

### **1.3** Organization of the Thesis

Subsequent chapters will explain the algorithms derived for prediction, tracking and retrodiction in detail. In Chapter 2 derived estimator for path constrained targets is given. It also consists of the techniques used to improve the prediction and tracking algorithm. Chapter 3 poses the retrodiction algorithm derived for path constrained targets where initially a retrodiction algorithm is derived and then later it is extended to path constrained targets. PCRLB for path constrained targets is given in 3.3. Simulation tests and results are given in Chapter 4 where one test is carried out in a simulated scenario and another test is carried out on real data gathered from exactEarth Inc. The author's conclusions are presented in Chapter 5 along with a discussion on possible future research directions.

# Chapter 2

# Path Constrained Estimator

Variable Structure Interacting Multiple Model (VS-IMM) estimator is developed based on IMM algorithm. But models in the mode set are fixed in IMM but it can vary based on constraints in VS-IMM. The proposed path constrained estimator developed in this research is extended on VS-IMM algorithm with path map information.

### 2.1 Path Constrained Estimator Algorithm

Let  $S_{k-1}$  be the segment in effect,  $A(k-1) = (M_1(k-1), M_2(k-1), ..., M_i(k-1), ...)$ be the mode set of the IMM estimator in the time interval (k-2, k-1]. Further  $S_k$  is the segment in effect during the time interval (k-1, k] and the mode set of the IMM estimator is A(k), which may or may not include the models from A(k-1). 1). Measurements are obtained by sensors with low revisit rates. In this scenario, the target may change from one to another segment within successively received measurements. Figure 2.1 shows that during the time interval (k-1, k], target is in two different segments. Proposed algorithm considers this issue and predicts the target state more precisely. Let  $(k - \tau)$  be the time at which the target changes the segment where  $0 < \tau < 1$ .

Figure 2.1: Mode changes at time  $k - \tau$  due to segment change

The steps of the tracking algorithm are:

#### Step 1 - Calculation of the mixing probabilities

The probability that mode  $M_i$  was in effect at (k-1) given that mode  $M_{i'}$  is in effect at  $(k-\tau)$  conditioned on  $Z_1^{k-1}$  is

$$\mu_{i|i'}(k-1|k-1) = P\{M_i|M_{i'}, Z_1^{k-1}\}$$
$$= \frac{1}{C_{i'}} P\{M_{i'}|M_i, Z_1^{k-1}\} P\{M_i|Z_1^{k-1}\}$$
(2.1)

The above mixing probabilities can be written as

$$\mu_{i|i'}(k-1|k-1) = \frac{1}{C_{i'}} \left[ p_{ii'}(S_{k-1}) \right] \mu_i(k-1) \qquad \forall i, \ \forall i'$$
(2.2)

where the normalizing constants are given by

$$C_{i'} = \sum_{M_i \in A(k-1)} [p_{ii'}(S_{k-1})] \ \mu_i(k-1) \qquad \forall i'$$
(2.3)

#### Step 2 - IMM Mixing

Mixed initial condition for the filter matched to  $M_{i'}(k-\tau)$  is computed as

$$\hat{x}^{0i'}(k-1|k-1) = \sum_{M_i \in A(k-1)} \hat{x}^i(k-1|k-1) \ \mu_{i|i'}(k-1|k-1) \quad \forall i'$$
(2.4)

The corresponding covariance is given by

$$P^{0i'}(k-1|k-1) = \sum_{M_i \in A(k-1)} \mu_{i|i'}(k-1|k-1) \left\{ \hat{x}^i(k-1|k-1) + [\hat{x}^i(k-1|k-1) - \hat{x}^{0i'}(k-1|k-1)] \right\}$$
$$\left[ \hat{x}^i(k-1|k-1) - \hat{x}^{0i'}(k-1|k-1) \right]^T \left\{ \begin{array}{c} \forall i' \end{array} \right\}$$
(2.5)

#### Step 3 - Mode Matched Filtering

The estimate  $\hat{x}^{0i'}(k-1|k-1)$  and covariance  $P^{0i'}(k-1|k-1)$  are used as input to the filter matched to  $M_{i'}$  to derive predicted state  $\hat{x}^{i'}(k-\tau|k-1)$  and covariance

$$P^{i'}(k-\tau|k-1).$$

$$p\{x(k-\tau)|M_{i'}, Z_1^{k-1}\} = \mathcal{N}\left[x(k-\tau); E[x(k-\tau)|M_{i'}, \hat{x}^{0i'}(k-1|k-1)], cov[.]\right]$$
(2.6)

This gives

$$\hat{x}^{i'}(k-\tau|k-1) = F^{i'}(k-\tau,k-1) \ \hat{x}^{0i'}(k-1|k-1)$$

$$\hat{P}^{i'}(k-\tau|k-1) = F^{i'}(k-\tau,k-1) \ \hat{P}^{0i'}(k-1|k-1) \ F^{i'}(k-\tau,k-1)^T$$

$$+ Q^{i'}(k-\tau,k-1)$$
(2.8)

The predicted state  $\hat{x}^{i'}(k-\tau|k-1)$  is fed to the filter matched to  $M_{j'}$  to compute the predicted state  $\hat{x}^{i'j'}(k|k-1)$  and covariance  $P^{i'j'}(k|k-1)$ .

$$p[x(k)|M_{j'}, M_{i'}, Z_1^{k-1}] = P[x(k)|x(k-\tau), M_{j'}, M_{i'}, Z_1^{k-1}] P[x(k-\tau)|M_{j'}, M_{i'}, Z_1^{k-1}]$$
$$= P[x(k)|x(k-\tau), M_{j'}, Z_1^{k-1}] P[x(k-\tau)|M_{i'}, Z_1^{k-1}]$$
(2.9)

Since there is a change in the direction of velocity at time  $(k - \tau)$  due to segment change, it has to be considered during the above derivation as well. A rotation matrix is used for this purpose. For e.g., in a two dimensional tracking scenario with target state  $\mathbf{x}(k)$  defined by the 4-dimensional vector  $\mathbf{x}(k) = [x(k) \ \dot{x}(k) \ y(k) \ \dot{y}(k)]'$  rotation matrix is given by

$$R = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\theta & 0 & -\sin\theta \\ 0 & 0 & 1 & 0 \\ 0 & \sin\theta & 0 & \cos\theta \end{bmatrix}$$
(2.10)

where  $\theta$  is the angle between the two segments in counter clockwise direction as shown in Figure 2.1.

Applying Gaussian distribution computation rules to (2.9) and incorporating the rotation matrix (R) gives the following equations for  $\hat{x}^{i'j'}(k|k-1)$  and  $\hat{P}^{i'j'}(k|k-1)$ 

$$\hat{x}^{i'j'}(k|k-1) = F^{j'}(k,k-\tau) \ R \ F^{i'}(k-\tau,k-1)\hat{x}^{0i'}(k-1|k-1)$$
(2.11)

$$\hat{P}^{i'j'}(k|k-1) = F^{j'}(k,k-\tau) R \left\{ F^{i'}(k-\tau,k-1)\hat{P}^{0i'}(k-1|k-1) F^{i'}(k-\tau,k-1)^T \right\}$$

$$+Q^{i'}(k-\tau,k-1) \bigg\} R^T F^{j'}(k,k-\tau)^T + Q^{j'}(k,k-\tau)$$
(2.12)

When measurements become available, updated state  $\hat{x}^{i'j'}(k|k)$  and covariance  $P^{i'j'}(k|k)$  are computed in a standard IMM method and the likelihood function corresponding to the above filtering processes are calculated by

$$\Lambda_{i'j'}(k) = P[z(k)|M_{j'}, M_{i'}, Z_1^{k-1}] \qquad \forall i', \forall j'$$
(2.13)

#### Step 4 - Mode probability updating

The probability of model  $(M_{i'}, M_{j'})$  being in effect during the time interval (k, k-1]

given measurement data up to k can be calculated as

$$\mu_{i'j'}(k|k) = P\{M_{j'}, M_{i'}|Z_1^k\}$$

$$= P\{M_{j'}, M_{i'}|z(k), Z_1^{k-1}\}$$

$$= \frac{1}{C_{i'j'}} P[z(k)|M_{j'}, M_{i'}, Z_1^{k-1}] P[M_{j'}|M_i', Z_1^{k-1}] P[M_i'|Z_1^{k-1}]$$

$$= \frac{1}{C_{i'j'}} \Lambda_{i'j'}(k) [p_{i'j'}(S_{k-1}, S_k)] \mu_{i'}(k-\tau) \qquad (2.14)$$

where  $\mu_{i'}(k-\tau)$  are

$$\mu_{i'}(k-\tau) = P\{M_{i'}|Z_1^{k-1}\}$$

$$= \sum_{M_i \in A(k-1)} P\{M_{i'}|M_i(k-1), Z_1^{k-1}\} P\{M_i|Z_1^{k-1}\}$$

$$= \sum_{M_i \in A(k-1)} [p_{ii'}(S_{k-1})] \mu_i(k-1)$$
(2.15)

### Step 5 - State estimate and covariance combination

The final state estimate and covariance are

$$\hat{x}(k|k) = \sum_{M_{j'}, M_{i'} \in A(k)} \hat{x}^{i'j'}(k|k) \ \mu_{i'j'}(k|k)$$
(2.16)

$$P(k|k) = \sum_{M_{j'}, M_{i'} \in A(k)} \mu_{i'j'}(k|k) \left\{ P^{i'j'}(k|k) + [\hat{x}^{i'j'}(k|k) - \hat{x}(k|k)] [\hat{x}^{i'j'}(k|k) - \hat{x}(k|k)]^T \right\}$$

$$(2.17)$$

Figure 2.2: Path constrained filtering (one cycle)

#### 2.1.1 Validation Test for Mode Set Adaptation

At each scan k, it is required to find out the possible segments and corresponding models to be added to the mode set for a target. A validation region test (Kirubarajan *et al.*, 2000) has to be carried out for this purpose. Since there are more than one mode in the mode set A(k-1), there are more than one predicted state estimate and covariance, i.e., no common predicted state estimate or covariance. To solve this, predicted state estimate and predicted covariance correspond to the largest determinant among the modules in A(k-1) is selected (Bar-Shalom and Li, 1995).

While carrying out the above test, another test is carried out for junctions. When a junction falls within the validation region, segment hypotheses (Section 2.1.4) are generated for each segment that falls within the validation region. A mode set is kept for each segment hypothesis and models corresponding to the segment is added to the respective mode set. But the problem with the above validation region is that there are instances where none of the junction falls within the validation region although the target is predicted to pass a junction. To overcome this problem, when none of the junction falls within the validation region, a test is carried out to check whether the predicted state falls outside the present segment or not. If it is still in the present segment, mode set will be kept as it is. But if it is not in the present segment, a new segment hypothesis is created for each segment connected with the present segment and updated with corresponding models.

### 2.1.2 Directional Process Noise

Since the targets are constrained to move along the path, uncertainty along the path is higher compared to the uncertainty orthogonal to the path. The concept of "directional process noise" (Bar-Shalom and Li, 1995) is used to handle the above mentioned issue. Figure 2.3 shows the directional process noise concept corresponding to the path constrained targets. The estimation is carried out in X-Y coordinate system, so the directional process noise along and orthogonal to the path has to be converted into a covariance matrix Q in X-Y frame. Let standard deviation of process noise along the path be  $\sigma_a$  and standard deviation in the orthogonal direction be  $\sigma_o$ . The conversion is done via (Yeddanapudi *et al.*, 1997)

$$Q = \begin{bmatrix} -\cos\psi & \sin\psi\\ \sin\psi & \cos\psi \end{bmatrix} \begin{bmatrix} \sigma_o^2 & 0\\ 0 & \sigma_a^2 \end{bmatrix} \begin{bmatrix} -\cos\psi & \sin\psi\\ \sin\psi & \cos\psi \end{bmatrix}$$
(2.18)

Figure 2.3: Directional process noise for path constrained targets

#### 2.1.3 Velocity Prediction During Segment Changes

Different segments may have different maximum velocities allowed based on terrain conditions. For example, maximum speed allowed in an urban area and rural area is not the same. Incorporating this maximum velocity constraint as a prior information in the prediction process can lead to a better estimate. Let target in a segment be  $S_{k-1}$  where maximum velocity is  $MV_{k-1}$  in time (k-1) and the target is predicted to be in different segment  $S_k$  with maximum velocity  $MV_k$  in time k. If the resultant velocity of the target is V(k-1|k-1) in time (k-1), the velocity in time k is predicted to be  $V(k|k-1) = \left(\frac{MV_k}{MV_{k-1}} V(k-1|k-1)\right)$  in the  $S_k$  segment direction. Here the assumption is target velocity change is proportional to the maximum velocity ratio and  $V(k-1|k-1) = \sqrt{\dot{x}(k-1|k-1)^2 + \dot{y}(k-1|k-1)^2}$ . Instead of this assumption, any other ratio that depends on the scenario can be integrated into proposed prediction/tracking algorithm as follows:

Let the ratio be r, then (2.10) is modified as

$$R = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & r \cos \theta & 0 & -r \sin \theta \\ 0 & 0 & 1 & 0 \\ 0 & r \sin \theta & 0 & r \cos \theta \end{bmatrix}$$
(2.19)

Since the proposed algorithm explicitly considers the segment change at time  $(k - \tau)$ , velocity prediction is incorporated into the proposed algorithm in step 3 of Section 2. It can be noted here that it is not possible to include the above velocity ratio information in the existing algorithms (Kirubarajan *et al.*, 2000), (Pannetier *et al.*, 2005).
#### 2.1.4 Hypothesis Generation Based on Segments

A concept of hypotheses for segments (Pannetier *et al.*, 2005) is used to handle the uncertainty in a junction. Assume a target moves in a segment  $S_{k-1}$  at time (k-1) and predicted state falls in more than one segment at time k, then for each segment a new segment hypothesis is generated. Now, the process of updating mode set and tracking are carried out for each segment hypothesis separately using a path constrained estimator. Consider a scenario where during the time interval (k-3, k-2]target moves in segment  $S_1$  and during the time interval (k-2, k-1] target has the possibility of moving in either segment  $S_2$  or  $S_3$ . Figure 2.4 shows segment hypothesis tree for the above scenario, where during time interval (k-2, k-1] one segment hypothesis is available and during the next time interval two segment hypotheses are available.

Denote the hypotheses available during the time interval (k-2, k-1] as  $\Psi(k-1) = (h'_1(k-1), h'_2(k-1)..., h'_i(k-1))$ . Similarly it can be written for the hypotheses available in time (k-1, k] as  $\Psi(k)$ . The segment hypothesis probability is given by

$$\mu_{h}(k) = P\{x(k) \in h | Z_{1}^{k}\}$$

$$= \frac{1}{c} P[z(k) | Z_{1}^{(k-1)}, x(k) \in h] P[x(k) \in h | Z_{1}^{k-1}]$$

$$= \frac{1}{c} \Delta_{h}(k) \sum_{h' \in \Psi(k-1)} P[x(k) \in h | x(k) \in h', Z_{1}^{k-1}] P[x(k) \in h' | Z_{1}^{k-1}]$$

$$= \frac{1}{c} \Delta_{h}(k) \sum_{h' \in \Psi(k-1)} p_{h',h} \mu_{h'}(k-1) \qquad (2.20)$$

where c is the normalization factor and  $\Psi(k-1)$  is segment hypothesis transition probability. The probability of  $\Delta_h(k)$  is shown in (Yeddanapudi *et al.*, 1997) as follows:

$$\Delta_{h}(k) = P\{Z_{1}^{k} | Z_{1}^{k-1}, x(k) \in h\} \quad \forall h \in \Psi(k)$$
  
=  $\sum_{M \in h} \Lambda_{M}(k) \ \mu_{M}(k|k-1)$  (2.21)

where M are the models belonging to the segments in segment hypothesis h and  $\mu_M(k|k-1)$  is the predicted mode probability.

Figure 2.4: Segment hypothesis tree

Since more than one hypotheses are available at a time, there should be a mechanism to select the best hypotheses at a given time. A sequential probability ratio test as in (Pannetier *et al.*, 2005) is carried out for this purpose.

# Chapter 3

# Retrodiction for Path Constrained Targets

Retrodiction is the estimation of the state at a time within the data time interval (Bar-Shalom *et al.*, 2001). Since path information determines the smoothness of the track, no retrodiction algorithms have been specifically developed for path constrained problems in literature. A retrodiction algorithm for path constrained targets is developed in this research considering available path map information. An approach of a backward iteration scheme to calculate the states of the targets at a previous time given all measurement information is followed. The iteration process is initialized by the present target state and follows the standard RTS fixed interval smoothing (Rauch *et al.*, 1965). In (Koch, 2000), fixed interval retrodiction to Multiple Hypothesis Tracking (MHT) applications employing IMM is given. The proposed algorithm here is an extended work of (Koch, 2000) with variable structure IMM for path constrained targets. While carrying out the tracking process, the mode set is updated at each segment change rather than at measurement receive time. This is considered

in the following derivation during mode matched smoothing step. During a segment change in the prediction process, velocity is changed and predicted according to the segment constraint (Section 2.1.3). The velocity prediction is handled with the help of a rotation matrix (2.19) in prediction. Derived retrodiction algorithm considers the above modifications in retrodiction process, which results in better retrodicted states during the segment changes. A general approach is given for Gaussian smoothing in (Deisenroth and Ohlsson, 2011) and the derivation of the retrodiction algorithm here complies with this general approach.

Subsection 3.1 gives the steps for variable structure IMM retrodiction algorithm without segment constraint. This is similar to the algorithm proposed in (Nandakumaran *et al.*, 2009) but differs in Step 3, mode matched retrodiction. Path constrained retrodiction algorithm is followed in subsection 3.2.

### 3.1 General Retrodiction Algorithm

Let  $A(t) = (M_1(t), ..., M_u(t), ...)$  and  $A(t+1) = (M_1(t+1), ..., M_v(t+1), ...)$ . The models in A(t) and A(t+1) can be different and we are interested in  $\hat{x}(t|k)$ , where t < k. The steps for the retrodiction algorithm are

#### Step 1 - Backward transition probability

$$b_{vu} = P(M_u | M_v, Z_1^k)$$
  
=  $\frac{1}{d_v} p_{uv} \mu_u(t|t)$  (3.1)

where  $d_v = \sum_{M_u \in A(t)} p_{uv} \ \mu_u(t|t)$ 

#### Step 2 - Backward mixing probability

$$\mu_{v|u}(t+1|k) = P(M_v|M_u, Z_1^k)$$
  
=  $\frac{1}{d_u} b_{vu} \ \mu_v(t+1|k)$  (3.2)

where  $d_u = \sum_{M_v \in A(t+1)} b_{vu} \ \mu_v(t+1|k)$ 

### Step 3 - Mode matched retrodiction

$$\hat{x}^{uv}(t|k) = \hat{x}^{u}(t|t) + A \left[\hat{x}^{v}(t+1|k) - \hat{x}^{uv}(t+1|t)\right]$$
(3.3)

$$P^{uv}(t|k) = P^{u}(t|t) + A \left[P^{v}(t+1|k) - P^{uv}(t+1|t)\right] A^{T}$$
(3.4)

where retrodiction gain A is given by

$$A = P^{u}(t|t) \left[F^{v}(t+1)\right]^{T} \left[F^{v}(t+1,t) P^{u}(t|t) F^{v}(t+1,t)^{T} + Q^{v}(t+1,t)\right]^{-1}$$
(3.5)

Further the terms  $\hat{x}^{uv}(t+1|t)$  and  $\hat{P}^{uv}(t+1|t)$  are written as

$$\hat{x}^{uv}(t+1|t) = F^v(t+1,t) \ \hat{x}^u(t|t) \tag{3.6}$$

$$P^{uv}(t|k) = F^{v}(t+1,t) P^{u}(t|t) F^{v}(t+1,t)^{T} + Q^{v}(t+1,t)$$
(3.7)

During the retrodiction process, this iteration step will be initiated with present target state  $\hat{x}^v(t+1|k) = \hat{x}^v(k|k)$ 

(3.9)

#### Step 4 - Mixing

$$\hat{x}^{u}(t|k) = \sum_{M_{v} \in A(t+1)} \hat{x}^{uv}(t|k) \ \mu_{v|u}(t+1|k)$$
(3.8)

$$\hat{P}^{u}(t|k) = \sum_{M_{v} \in A(t+1)} \mu_{v|u}(t+1|k) \left( P^{uv}(t|k) + [\hat{x}^{uv}(t|k) - \hat{x}^{u}(t|k)] \left[ \hat{x}^{uv}(t|k) - \hat{x}^{u}(t|k) \right]^{T} \right)$$

#### Step 5 - Smoothed mode Probability

$$\mu_u(t|k) = \frac{1}{f} \Lambda^u(t|k) \ \mu_u(t|t)$$
(3.10)

where f is a normalizing constant and

$$\Lambda^{u}(t|k) = \sum_{M_{v} \in A(t+1)} p_{uv} \mathcal{N}\left(\hat{x}^{v}(t+1|k); \hat{x}^{uv}(t+1|t), P^{uv}(t+1|t)\right)$$
(3.11)

#### Step 6 - Smoothed Estimate

$$\hat{x}(t|k) = \sum_{M_u \in A(k)} \mu_u(t|k) \ \hat{x}^u(t|k)$$
(3.12)

$$\hat{P}(t|k) = \sum_{M_u \in A(k)} \mu_u(t|k) \left( \hat{P}^u(t|k) + [\hat{x}^u(t|k) - \hat{x}(t|k)] [\hat{x}^u(t|k) - \hat{x}(t|k)]^T \right)$$
(3.13)

# 3.2 Path Constrained Retrodiction Algorithm

When there is a segment change between successively received measurement time, above retrodiction algorithm is modified to accommodate the segment changes and the corresponding motion model changes. The steps of the modified algorithm are: Let mode in effect during the time interval  $(t, t + \delta]$  as  $M_{u'}$  and during  $(t + \delta, t + 1]$ as  $M_{v'}$  as shown in Figure 3.1, where  $M_{u'}, M_{v'} \in A(t + 1)$ 

Figure 3.1: Mode changes at time  $t + \delta$  due to segment change

#### Step 1 - Backward transition probability

$$b_{(v'u')u} = P(M_u | M_{(v'u')}, Z_1^k)$$
  
=  $\frac{1}{d_{(v'u')}} p_{u'v} p_{uu'} \mu_u(t|t)$  (3.14)

where  $d_{(v'u')} = \sum_{M_u \in A(t)} p_{u'v} p_{uu'} \mu_u(t|t)$ 

#### Step 2 - Backward mixing probability

$$\mu_{(v'u')|u}(t+1|k) = P(M_{v'}, M_{u'}|M_u, Z_1^k)$$
  
=  $\frac{1}{d_u} b_{(v'u')u} \mu_{(v'u')}(t+1|k)$  (3.15)

where  $d_u = \sum_{M_{v'}, M_{u'} \in A(t)} b_{(v'u')u} \ \mu_{(v'u')}(t+1|k)$ 

### Step 3 - Mode matched retrodiction

$$\hat{x}^{u(u'v')}(t|k) = \hat{x}^{u}(t|t) + A \left[ \hat{x}^{u'v'}(t+1|k) - \hat{x}^{u(u'v')}(t+1|t) \right]$$
(3.16)

$$P^{u(u'v')}(t|k) = P^{u}(t|t) + A \left[ P^{u'v}(t+1|k) - P^{u(u'v')}(t+1|t) \right] A^{T}$$
(3.17)

where retrodiction gain A is given by

$$A = P^{u}(t|t) \left[ F^{v'}(t+1,t+\delta) \ R \ F^{u'}(t+\delta,t) \right]^{T} \left[ P^{u(u'v')}(t+1|t) \right]^{-1}$$
(3.18)

Further the terms  $\hat{x}^{uv}(t+1|t)$  and  $P^{uv}(t+1|t)$  can be derived as

$$\hat{x}^{u(u'v')}(t+1|t) = F^{v'}(t+1,t+\delta) R F^{u'}(t+\delta,t) \hat{x}^{u}(t|t)$$

$$P^{u(u'v')}(t+1|t) = F^{v'}(t+1,t+\delta) R \left\{ F^{u'}(t+\delta,t) P^{u}(t|t) F^{u'}(t+\delta,t)^{T} + Q^{u'}(t+\delta,t) \right\} R^{T} F^{v'}(t+1,t+\delta)^{T} + Q^{v'}(t+1,t+\delta)$$
(3.19)
(3.19)
(3.19)
(3.19)

Here all terms except  $\hat{x}^{u'v'}(t+1|k)$  and  $P^{u'v}(t+1|k)$  can be calculated and stored during the prediction process to be used for retrodiction.

#### Step 4 - Mixing

$$\hat{x}^{u}(t|k) = \sum_{M_{v'}, M_{u'} \in A(t+1)} \hat{x}^{u(u'v')}(t|k) \ \mu_{(v'u')|u}(t+1|k)$$
(3.21)
$$\hat{P}^{u}(t|k) = \sum_{M_{v'}, M_{u'} \in A(t+1)} \mu_{(v'u')|u}(t+1|k) \left( P^{u(u'v')}(t|k) + [\hat{x}^{u(u'v')}(t|k) - \hat{x}^{u}(t|k)] \left[ \hat{x}^{u(u'v')}(t|k) - \hat{x}^{u}(t|k) \right]^{T} \right)$$
(3.22)

#### Step 5 - Smoothed mode Probability

$$\mu_u(t|k) = \frac{1}{f} \Lambda^u(t|k) \ \mu_u(t|t)$$
(3.23)

where f is a normalizing constant and

$$\Lambda^{u}(t|k) = \sum_{M_{v'}, M_{u'} \in A(t+1)} p_{u'v'} p_{uu'} \mathcal{N}\left(\hat{x}^{u'v'}(t+1|k); \hat{x}^{u(u'v')}(t+1|t), P^{u(u'v')}(t+1|t)\right)$$
(3.24)

#### Step 6 - Smoothed Estimate

$$\hat{x}(t|k) = \sum_{M_u \in A(k)} \mu_u(t|k) \ \hat{x}^u(t|k)$$
(3.25)

$$\hat{P}(t|k) = \sum_{M_u \in A(k)} \mu_u(t|k) \left( \hat{P}^u(t|k) + [\hat{x}^u(t|k) - \hat{x}(t|k)] [\hat{x}^u(t|k) - \hat{x}(t|k)]^T \right)$$
(3.26)

# 3.3 Posterior Cramer Rao Lower Bound for Path Constrained Targets

Posterior Cramer Rao Lower Bound (PCRLB) gives a lower bound on the error covariance and it is defined by inverse,  $J(k)^{-1}$  of the Fisher information matrix (FIM)

$$\mathbf{E}[[\hat{x}(k) - x(k)] \ [\hat{x}(k) - x(k)]^T] \ge J(k)^{-1}$$
(3.27)

where **E** denotes expectation over  $(x(k), Z_1^k)$ .

For a linear system without measurement origin uncertainty, J(k+1) can be

written as sum of (Hernandez *et al.*, 2004)

$$J(k+1) = [Q(k) + F(k) \ J(k)^{-1} \ F(k)^T]^{-1} + \sum_{i=1}^n \mathbf{E}(H^i(k)\Sigma^i(k)^{-1}H^i(k)^T) \quad (3.28)$$

where n is the number of sensors.

However, it has been observed that the PCRLB can be overly optimistic in certain cases (Horridge and Hernandez, 2003), (Hernandez, 2003) and (Hernandez *et al.*, 2008). In (Hernandez, 2003) it is shown that PCRLB for tracking road-based vehicles using ground moving target indicator (GMTI) sensors were over-optimistic, due to the potential multi-modality of the target distribution at each junction. It is shown in (Hernandez *et al.*, 2008) that PCRLB bound for tracking manoeuvering target with Markovian switching dynamics produce an overly optimistic lower bound due to the assumption of implicitly assumed known manoeuvres. As a result instead of PCRLB, a performance measure is given for Markovian switching dynamic systems in (Hernandez *et al.*, 2008). So to evaluate the proposed path constrained algorithm with PCRLB, a single model is considered for developing the bound for path constrained targets instead of multi-model Markovian switching dynamics.

The challenging part in path constrained tracking PCRLB is to consider the structure of the road network and the constraints imposed on the target motion. In (Hernandez, 2003), when a target reaches a junction all possible path available at the junction are incorporated for the PCRLB calculation, which resulted in over optimistic PCRLB. But the path prediction algorithm developed in this paper considers sequence of path as different segment hypotheses as described in subsection 2.1.4. This allows PCRLB to be derived for each segment hypothesis separately and based on the technique described in (Hernandez, 2003), PCRLB for path constrained targets is developed with single model tracking.

Consider Figure 2.1, and let the time duration between successive scan k and (k+1) be T, and time taken to reach the intersection point is T1. Then the equivalent state transition matrix,  $F_{eq}$ , required for the PCRLB calculation when there is a segment change in target motion is given by

$$F_{eq} = F(T - T1) R F(T1)$$
(3.29)

where F(T1) is the state transition matrix correspond to a motion model for time duration T1 in segment  $S_{k-1}$ , F(T-T1) correspond to a motion model for time duration (T-T1) in segment  $S_k$  and R is the rotation matrix given in (2.10). Process noise covariance Q(k) is replaced with directional process noise covariance in (3.28) and when there is a segment change in the target motion it can be shown that the equivalent process noise covariance,  $Q_{eq}$ , is given by

$$Q_{eq} = F(T - T1) R Q(T1) R^T F(T - T1)^T + Q(T - T1)$$
(3.30)

where Q(T1) is the directional process noise for time duration T1 and Q(T - T1) is the directional process noise for time duration (T - T1).

Further PCRLB for retrodiction without measurement origin uncertainty is same as RTS equation (Simandl *et al.*, 2001). Retrodiction algorithm developed in this paper for path constrained targets follows the concept of RTS equation and it can be shown that for a single model retrodiction PCRLB for path constrained targets can be derived from single model version of (3.16) and (3.17).

# Chapter 4

# Simulation Studies and Results

To validate the proposed algorithms, simulations are carried out and analyzed. The simulated scenario based test is given in section 4.1 and a test on the real data gathered from exactEarth Inc is given in section 4.2.

### 4.1 Simulation Test

The path map network used to demonstrate the simulation is shown in Figure 4.1. There are five segments and six way-points with two junctions. For simulation purposes it is assumed that probability of a target moving to segment  $S_2$  from  $S_1$  is 0.2 and probability of a target moving to segment  $S_3$  from  $S_1$  is 0.8. Similarly probability for  $S_3$  to  $S_4$  is 0.2 and  $S_3$  to  $S_5$  is 0.8. With this segment transition probabilities target trajectories are generated for 100 Monto carlo runs. Target's dynamic variation is given for segment sequence  $(S_1, S_3, S_5)$  in Figure 4.2 where target reaches the intersection points at approximately 510s and 1650s. Target state  $\mathbf{x}(k)$  is defined by the 4-dimensional vector  $\mathbf{x}(k) = [x(k) \ \dot{x}(k) \ y(k) \ \dot{y}(k)]^T$  where x(k) and  $\dot{x}(k)$  are position and velocity of a target in X direction. The sensor measurement consists of target's position in X and Y direction resulting in observation matrix

$$H(k) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$
(4.1)

Second order white noise acceleration models are used for modeling the motion of target, where second order piecewise white noise acceleration model state transition matrix F(k, k - 1) is given by

$$F(k,k-1) = \begin{bmatrix} 1 & T & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & T \\ 0 & 0 & 0 & 1 \end{bmatrix}$$
(4.2)

and vector gain  $\Gamma(k, k-1)$  is given by

$$\Gamma(k, k-1) = \begin{bmatrix} T^2/2 & 0 \\ T & 0 \\ 0 & T^2/2 \\ 0 & T \end{bmatrix}$$
(4.3)

here T is the time duration between scan (k - 1) and k. The fixed mode IMM estimator, which is used for comparing simulation results with proposed algorithm, consists of two second order white noise acceleration models with equal process noise levels in both the X and Y directions. For these filters,  $\sigma_x = \sigma_y$  were 0.05 and 0.5 m/s<sup>2</sup>, which corresponds to constant velocity and maneuver modes, respectively. The proposed path constrained filter used two models for the path constrained motion. Constrained constant velocity model defined by  $\sigma_a = 0.05 \text{ m/s}^2$  and  $\sigma_o = 0.002 \text{ m/s}^2$ , and a manoeuvre model defined by  $\sigma_a = 0.5 \text{ m/s}^2$  and  $\sigma_o = 0.002 \text{ m/s}^2$ . Sensor revisit interval is 60 seconds with error covariance of  $400\text{m}^2$  in both X and Y position. A single target with zero process noise is considered with the detection probability equals to unity and false alarm probability equals to zero. The sojourn time (Bar-Shalom *et al.*, 2001) for the above models are 100s. The benefits of using the proposed algorithm are quantified using the results from 100 Monte Carlo runs.

Figure 4.1: Path map for simulation

Figure 4.2: Target dynamics variation

There are three segment hypotheses possible for this scenario. The segment sequences of these segment hypotheses are  $(S_1, S_2), (S_1, S_3, S_4)$  and  $(S_1, S_3, S_5)$ . But when the measurements become available, hypotheses will be pruned based on the sequential probability ratio test. The simulation results given here are based on the best hypothesis selected from each Monte Carlo run. Figure 4.3 shows the Root Mean Square Error (RMSE) in position for tracking. Proposed algorithm is compared against fixed mode IMM, variable structure IMM and measurements. Variable structure IMM used the same motion models as proposed path constrained estimator. Proposed path constrained algorithm performs better than the other algorithms due to the better prediction mechanism, where additional prior information of path map

and imposed constraints are used. For instance, predicted state position was close to the segment  $S_3$  in segment sequence  $(S_1, S_3, S_4)$  when the target was approaching the intersection between segment  $S_1$  and  $S_3$  where IMM prediction mechanism will predict it in an off-path position. Since same motion models are used for path constrained algorithm and VS-IMM, position RMSE is same except the region near the junctions. When a target is within the validation gate (Kirubarajan et al., 2000) of a junction, all the motion models corresponding to all possible segments associated to the junction are added to the mode set in VS-IMM. For e.g., when a target is within the validation gate of the first junction, all motion models corresponding to segments  $S_1, S_2$  and  $S_3$  are added. The problem with this method is if the target is following segment sequence  $(S_1, S_3, S_4)$ , adding the motion models corresponding to segment  $S_2$  is increasing the position error and position uncertainty. Because of the models which are actually not relevant to the target motion also added, the position error becomes larger near the junctions for VS-IMM. But the proposed algorithm generates segment hypotheses (2.1.4) and modes are added based on the segments involved in a segment hypothesis. For e.g., when the target is closer to the first junction two hypotheses with segment sequences  $(S_1, S_2)$  and  $(S_1, S_3)$  will be generated and mode set will be updated for each segment hypothesis. This segment hypothesis approach with prior information of maximum velocity for a segment, results in better performance in position RMSE (Figure 4.3) for path constrained algorithm over VS-IMM near the junctions. Further it can be seen (Figure 4.3) that fixed mode IMM performs slightly better than the measurements for the above scenario with given fixed mode models. But when the process noise of the fixed mode IMM models are increased the performance of fixed mode IMM degrades as expected.

Figure 4.4 shows the Root Mean Square Error (RMSE) in velocity for tracking. The improvement in velocity RMSE is due to the velocity rotation, maximum velocity ratio and segment hypothesis approach, which are considered during the prediction. For example, when a target moves from  $S_1$  to  $S_3$ , direction of the velocity changes by 30 degrees and velocity is increased by 1.5 times. These changes are captured by the algorithm in the introduced rotation matrix but not in the standard IMM structure or VS-IMM, which results in more visible difference between algorithms. The better performance of the path constrained algorithm and VS-IMM over fixed mode IMM during the other time intervals is due to the directional process noise models used in VS-IMM and proposed algorithm.

Figure 4.3: RMS position errors for estimators

Figure 4.4: RMS velocity errors for estimators

Figure 4.5 and 4.6 shows root mean square error (RMSE) in position and velocity respectively for retrodiction compared with fixed interval IMM retrodiction algorithm (Koch, 2000). It is clearly seen that the IMM retrodiction algorithm shows a degraded performance in the junction compared to the proposed retrodiction algorithm. It is due to the predicted state (3.19) and retrodiction gain (3.18) in path constrained retrodiction algorithm are calculated considering the segment change and motion model change in the junctions where IMM retrodiction algorithm does not. As a result, a spike is observed during the intersection points. It has to be noted that the predicted state (3.19) and retrodiction gain (3.18) can be calculated and stored during the prediction stage to reduce the computational load during retrodiction process though it increases the memory load. During the other time intervals, due to the advantage of directional process noise concept better performance of proposed retrodiction algorithm is observed over the fixed interval IMM retrodiction algorithm, which used the estimates from fixed mode IMM.

Figure 4.5: RMS position errors for retrodiction

Figure 4.6: RMS velocity errors for retrodiction

Figure 4.7 and Figure 4.8 shows the comparison between the proposed tracking and proposed retrodiction algorithms where it can be clearly seen the improvement of retrodiction algorithm compared to the tracking algorithm over the whole time period.

Figure 4.7: RMS position errors comparison for proposed algorithms

Figure 4.8: RMS velocity errors comparison for proposed algorithms

Figure 4.9 shows the PCRLB bound for the tracking algorithm compared to the proposed path constrained algorithm's RMSE. PCRLB is calculated here with a single constant velocity motion model and the proposed tracking algorithm RMSE lies within the bound of PCRLB. Table 4.1 shows the average performance metrics in summary for the above simulations carried out. Based on these observations, one can rank the algorithms as follows(in order of increasing performance):

- 1. Fixed mode IMM
- 2. Path constrained filter
- 3. Retrodiction algorithm IMM-MHT
- 4. Retrodiction algorithm path constrained filter

Figure 4.9: PCRLB position comparison

Further, the computational load of the proposed path constrained algorithm is 2%

Filter	RMS pos. error(m)	RMS vel. error(m/s)
Fixed mode IMM	27.85	1.56
Path constrained filter	24.78	1.02
Retrodiction IMM-MHT	23.46	0.93
Retrodiction path constrained filter	18.98	0.60

Table 4.1: Average performance metrics

higher than the VS-IMM algorithm and proposed retrodiction algorithm is 5% higher than the fixed mode retrodiction IMM algorithm.

### 4.2 Real Data Test

Satellite-based AIS data is used for this test. This data corresponds to the vessels in region close to Indonesia and collected during September, 2011. Figure 4.10 shows the location (from 'Google Maps') corresponding to the above region. Since it is a path constrained problem, a path map should be available as a priori information. Due to the unavailability of shipping lanes in the corresponding region, latitude and longitude measurements from the given data set file is used to generate the path map. Figure 4.11 shows the whole measurement set plotted and this figure is used to generate the path map. But Matlab can not handle thousands of targets with the required plotting facility for prediction and retrodiction, due to that a specific area is selected for simulation as shown in the Figure 4.11.

Figure 4.12 shows the path map developed manually with 8 way-points and 7 segments for this test. Initially around 25 targets close to the selected area are taken to predict and track. Then two targets are selected to run and get the RMS position errors.

Figure 4.10: Location (Google maps)

Figure 4.11: Whole measurements plot

Figure 4.12: Path map with segments and way points

The data set selected for the testing purpose has measurements spanning around 33 hours. Figure 4.13 shows the tracks from the 25 targets over the time with prediction algorithm. Here prediction is carried out every 300s which can be changed according to the requirement. Figure 4.14 shows the tracks from the interested two targets where the first target was moving in Segment 3 in the direction of way-point 4 and the second target is in segment 2 and moving towards way-point 3. Above two targets moved over 1000 km and 1200 km in our local X-Y framework and generated four and three measurements respectively during the above time interval.

Figure 4.13: Tracks from 25 targets

Figure 4.14: Tracks from prediction

The tracks from the above test (Figure 4.14) is tested with retrodiction algorithm and Figure 4.15 shows the retrodicted tracks.

Figure 4.15: Tracks from retrodiction

To get the root mean square error (RMSE) for position estimate of our prediction and retrodiction algorithm, truth file for the above scenario is required. But in real scenarios it is not possible to get the truth values. So retrodicted tracks are kept as truth and RMSE test is carried out. Figure 4.16 shows the RMS position errors for both targets. It can be seen that, when the measurements are received the position RMSE is reduced and on average the position RMSE is around 17km. But when considering the distances these targets traveled and given only seven measurements received over this 34 hour period time, this value can be expected.

Figure 4.16: RMS position errors comparison

# Chapter 5

# **Conclusions and Future Work**

# 5.1 Conclusions

In this thesis, new tracking and retrodiction algorithms for path constrained targets are presented. As a target moves along a constrained path with different segment constraints, measurements are updated by sensor with low revisit rate. But target changes its motion due to segment constraints in between successive measurements. This results in a poor performance of existing algorithms due to not incorporating the path map information. The proposed tracking algorithm uses a prediction technique considering the segment change and the time taken to reach a junction. During prediction near the junctions, possible velocity change also considered for each segment to give a better estimate. A retrodiction algorithm considering the path map also developed in this paper based on (Rauch *et al.*, 1965) and (Koch, 2000). The retrodiction algorithm developed here supports the segment change and associated motion model changes in a junction. The results shows that the proposed algorithm in tracking and retrodiction performs better compared to the other algorithms in literature. The better performance of tracking algorithm is due to the prediction algorithm, which considers the path map information. Further already existing retrodiction algorithms does not consider the segment change explicitly as in the proposed retrodiction algorithm, resulting in a lower RMS error in position and velocity during retrodiction compared to the existing algorithms.

### 5.2 Future Work

The proposed algorithms could be extended to data association problems where the assumptions of zero false alarms and unity probability of detection can be relaxed. Further uncertainty in way-points and segments can also be included in path map information. Incorporating the above uncertainty information will increase the use-fulness of the proposed algorithms in real data applications. Finally building the path map information automatically from the real data would be a great area to explore. It will take the applications of proposed prediction and retrodiction algorithms to the next level.

# Appendix A

# **Algorithm Derivations**

### A.0.1 Filtering Algorithm Derivation

Derivation for path constrained target estimator is given here.

$$P[x(k)|Z_1^k] = \sum_{M_{j'}, M_{i'} \in A(k)} P[x(k)|M_{j'}, M_{i'}, Z_1^k)] P[M_{j'}, M_{i'}|Z_1^k]$$
(A.1)

 $\operatorname{consider}$ 

$$P[x(k)|M_{j'}, M_{i'}, Z_1^k)] = \frac{P[Z(k)|x(k), M_{j'}, M_{i'}]P[x(k)|M_{j'}, M_{i'}, Z_1^{k-1}]}{P[z(k)|M_{j'}, M_{i'}, Z_1^{k-1}]}$$
(A.2)

where  $P[z(k)|M_{j'}, M_{i'}, Z_1^{k-1}]$  is the likelihood and  $P[x(k)|M_{j'}, M_{i'}, Z_1^{k-1}]$  is the prior. The prior can be extended as follows

$$P[x(k)|M_{j'}, M_{i'}, Z_1^{k-1}] = P[x(k)|x(k-\tau), M_{j'}, M_{i'}, Z_1^{k-1}] P[x(k-\tau)|M_{j'}, M_{i'}, Z_1^{k-1}]$$
(A.3)

Consider the second term in the prior

$$P[x(k-\tau)|M_{j'}, M_{i'}, Z_1^{k-1}] = P[x(k-\tau)|M_{i'}, Z_1^{k-1}]$$
(A.4)

which can be written according to (Bar-Shalom et al., 2001) as

$$P[x(k-\tau)|M_{i'}, Z_1^{k-1}] = \mathcal{N}\left((x(k-\tau); E[x(k-\tau)|M_{i'}, \sum_{M_i \in A(k-1)} \hat{x}^i(k-1|k-1) \ \mu_{i|i'}(k-1|k-1)], Cov[.]\right)$$
(A.5)

where

$$\mu_{i|i'}(k-1|k-1) = P\{M_i|M_{i'}, Z_1^{k-1}\}$$
(A.6)

Now consider the first term in the prior

$$P[x(k)|x(k-\tau), M_{j'}, M_{i'}, Z_1^{k-1}] = P[x(k)|x(k-\tau), M_{j'}]$$
(A.7)

Now consider the following

$$P[M_{i'}, M_{j'}|Z_1^k)] = P[M_{i'}, M_{j'}|z(k), Z_1^{k-1})]$$
  
=  $\frac{1}{C_{i'j'}} P[z(k)|M_{j'}, M_{i'}, Z_1^{k-1}] P[M_{j'}|M_i', Z_1^{k-1}] P[M_i'|Z_1^{k-1}]$   
=  $\frac{1}{C_{i'j'}} \Lambda_{i'j'}(k) [p_{i'j'}(S_{k-1}, S_k)] \mu_{i'}(k - \tau)$  (A.8)

where

$$\mu_{i'}(k-\tau) = P\{M_{i'}|Z_1^{k-1}\}$$
  
=  $\sum_{M_i \in A(k-1)} P\{M_{i'}|M_i, Z_1^{k-1}\} P\{M_i|Z_1^{k-1}\}$   
=  $\sum_{M_i \in A(k-1)} [p_{ii'}(S_{k-1})] \mu_i(k-1)$  (A.9)

### A.0.2 Retrodiction Algorithm Derivation

This part presents algorithm derivation of retrodiction for variable structure IMM without any constraints. This is similar to the algorithm proposed in (Nandakumaran *et al.*, 2009) but differs in mode matched retrodiction.

Let  $A(t) = (M_1(t), ..., M_u(t), ...)$  and  $A(t+1) = (M_1(t+1), ..., M_v(t+1), ...)$ 

Smoothed density  $P[x(t)|Z_1^k]$  is required where t < k. It can be written as

$$P[x(t)|Z_1^k] = \sum_{M_u \in A(t)} P[x(t)|M_u, Z_1^k] P[M_u|Z_1^k]$$
(A.10)

The first term in (A.10) can be written as

$$P[x(t)|M_u, Z_1^k] = \sum_{M_v \in A(t+1)} P[x(t)|M_u, M_v, Z_1^k] P[M_v|M_u, Z_1^k]$$
(A.11)

Using the total probability theorem and the Bayes' rule the density  $P[x(t)|M_u, Z_1^k]$ can be simplified as follows
$$P[x(t)|M_u, M_v, Z_1^k] = \int P[x(t), x(t+1)|M_u, M_v, Z_1^k] dx_{t+1}$$

$$= \int P[x(t)|x(t+1), M_u, M_v, Z_1^k] P[x(t+1)|M_u, M_v, Z_1^k] dx_{t+1}$$
(A.12)

(A.13)  
= 
$$\int P[x(t)|x(t+1), M_u, M_v, Z_1^t] P[x(t+1)|M_v, Z_1^k] dx_{t+1}$$
  
(A.14)

$$= \int \frac{P[x(t+1)|x(t), M_u, M_v, Z_1^t] P[x(t)|M_u, Z_1^t]}{P[x(t+1)|M_u, M_v, Z_1^t]}$$

$$P[x(t+1)|M_v, Z_1^k] dx_{t+1}$$
(A.15)

In the above derivation,  $P[x(t)|x(t+1), M_u, M_v, Z_1^k]$  is replaced with  $P[x(t)|x(t+1), M_u, M_v, Z_1^t]$  and  $P[x(t)|M_u, Z_1^t]$  is the filtered mode conditioned density. The term  $P[x(t+1)|M_v, Z_1^k]$  is the smoothed density at time (t+1) given the mode  $M_v$  and the term in the denominator is constant. Using the Gaussian distribution computation rules, we can write  $P[x(t+1)|x(t), M_u, M_v, Z_1^t] P[x(t)|M_u, Z_1^t]$  in (A.15) as follows

$$P[x(t+1)|x(t), M_u, M_v, Z_1^t] P[x(t)|M_u, Z_1^t] = P[x(t+1), x(t)|M_u, M_v, Z_1^t]$$

$$= \mathcal{N}\left( \begin{bmatrix} x(t) \\ x(t+1) \end{bmatrix} \middle| \begin{bmatrix} \hat{x}^u(t|t) \\ F^v(t+1,t) \ \hat{x}^u(t|t) \end{bmatrix},$$

$$\begin{bmatrix} P^u(t|t) & P^u(t|t) \ F^v(t+1,t)^T \\ P^u(t|t) \ F^v(t+1,t) \ F^v(t+1,t) \ F^v(t+1,t)^T + Q_v(t|t) \end{bmatrix} \right)$$
(A.17)

In (A.14) now consider the first term

$$P[x(t)|x(t+1), M_u, M_v, Z_1^t] = \mathcal{N}(x(t)|m, P)$$
(A.18)

where

$$m = \hat{x}^{u}(t|t) + A \ (x(t+1) - F^{v}(t+1,t) \ \hat{x}^{u}(t|t))$$
(A.19)

$$P = P^{u}(t|t) - A \left[ F^{v}(t+1,t) P^{u}(t|t) F^{v}(t+1,t)^{T} + Q_{v}(t|t) \right] A^{T}$$
(A.20)

where

$$A = P^{u}(t|t) F^{v}(t+1,t)^{T} \left[ F^{v}(t+1,t) P^{u}(t|t) F^{v}(t+1,t)^{T} + Q_{v}(t|t) \right]^{-1}$$
(A.21)

Now from (A.12), the joint distribution of x(t) and x(t+1) given all the measurement is

$$P[x(t), x(t+1)|M_u, M_v, Z_1^k]$$
  
=  $P[x(t)|x(t+1), M_u, M_v, Z_1^k] P[x(t+1)|M_u, M_v, Z_1^k]$  (A.22)

$$= \mathcal{N}(x(t)|m, P)\mathcal{N}(x(t+1)|\hat{x}^{v}(t+1|k), P^{v}(t+1|k))$$
(A.23)

$$= \mathcal{N}\left( \begin{bmatrix} x(t+1) \\ x(t) \end{bmatrix} \middle| \begin{bmatrix} \hat{x}^{v}(t+1|k) \\ \hat{x}^{u}(t|t) + A (\hat{x}^{v}(t+1|k) - F^{v}(t+1,t) \hat{x}^{u}(t|t)) \end{bmatrix}, \\ \begin{bmatrix} P^{v}(t+1|k) & P^{v}(t+1|k) A^{T} \\ A P^{v}(t+1|k) & A P A^{T} + P \end{bmatrix} \right)$$
(A.24)

So based on the above derivation, mode matched smoothing mean and covariance

are given by (Rauch et al., 1965)

$$\hat{x}^{uv}(t|k) = \hat{x}^{u}(t|t) + A \left[ \hat{x}^{v}(t+1|k) - \hat{x}^{uv}(t+1|t) \right]$$
(A.25)

$$P^{uv}(t|k) = P^{u}(t|t) + A \left[ P^{v}(t+1|k) - P^{uv}(t+1|t) \right] A^{T}$$
(A.26)

where  $A = P^{u}(t|t) F^{v}(t+1)^{T} [F^{v}(t+1) P^{u}(t|t) F^{v}(t+1)^{T} + Q^{v}(t+1)]^{-1}$ . Further the terms  $\hat{x}^{uv}(t+1|t)$  and  $\hat{P}^{uv}(t+1|t)$  are written as

$$\hat{x}^{uv}(t+1|t) = F^v(t+1) \ \hat{x}^u(t|t) \tag{A.27}$$

$$P^{uv}(t|k) = F^{v}(t+1) P^{u}(t|t) F^{v}(t+1)^{T} + Q^{v}(t+1)$$
(A.28)

All other derivations are same as in (Nandakumaran *et al.*, 2009) except the derivation for  $P[M_u|Z_1^k]$  which can be written as

$$P[M_u|Z_1^k] \simeq P(M_u|\Upsilon_{t+1|k}, Z_1^t) \tag{A.29}$$

$$= \frac{1}{f} P(\Upsilon_{t+1|k}|M_u, Z_1^t) \ P(M_u|Z_1^t)$$
(A.30)

where  $\Upsilon_{t+1|k}$  is sufficient statistic for the measurement set  $Z_{t+1}^k$ . The normalizing constant is given by

$$f = \sum_{M_u \in A(t)} P(\Upsilon_{t+1|k} | M_u, Z_1^t) \ P(M_u | Z_1^t)$$
(A.31)

 $P(\Upsilon_{t+1|k}|M_u, Z_1^t)$  in (A.29) can be written as

$$P(\Upsilon_{t+1|k}|M_u, Z_1^t) = \sum_{M_v \in A(t+1)} P[(\Upsilon_{t+1|k}|M_v, M_u, Z_1^t] P[M_v|M_u, Z_1^t]$$
(A.32)

$$= \sum_{M_v \in A(t+1)} P[(\Upsilon_{t+1|k} | \Upsilon_{t|t}, M_v, M_u] [M_v | M_u]$$
(A.33)

$$= \sum_{M_v \in A(t+1)} p_{uv} \mathcal{N}(\Upsilon_{t+1|k}|\Upsilon_{t|t})$$
(A.34)

## A.0.3 Retrodiction Algorithm Derivation for Path Constrained Targets

The above derivation is extended to include the path segment change during retrodiction process as follows. Let  $A(t) = (M_1(t), M_2(t), ..., M_u(t), ...)$  is the mode set in the time interval (t - 1, t].  $t + \delta$  is the time at which target changes the segment where  $0 < \delta < 1$ . Further denote the mode in effect during the time interval  $(t, t + \delta]$ as  $M_{u'}$  and during  $(t + \delta, t + 1]$  as  $M_{v'}$  where  $M_{u'}, M_{v'} \in A(t + 1)$ 

$$P[x(t)|Z_1^k] = \sum_{\forall M_u} P[x(t)|M_u, Z_1^k] P[M_u|Z_1^k]$$
(A.35)

The first term in (A.35) can be written as

$$P[x(t)|M_u, Z_1^k] = \sum_{M_{u'}M_{v'} \in A(t+1)} P[x(t)|M_u, M_{u'}, M_{v'}, Z_1^k] P[M_{u'}, M_{v'}|M_u, Z_1^k]$$
(A.36)

we can write  $P[x(t)|M_u, M_{u'}, M_{v'}, Z_1^k]$  as follows

$$P[x(t)|M_u, M_{u'}, M_{v'}, Z_1^k] = \int \frac{P[x(t+1)|x(t), M_u, M_{u'}, M_{v'}, Z_1^t] P[x(t)|M_u, Z_1^t]}{P[x(t+1)|M_u, M_{u'}, M_{v'}, Z_1^t]}$$

$$P[x(t+1)|M_{u'}, M_{v'}, Z_1^k] dx_{t+1}$$
(A.37)

Based on (A.37), mode matched filtering equation can be written as follows

$$\hat{x}^{u(u'v')}(t|k) = \hat{x}^{u}(t|t) + A \left[ \hat{x}^{u'v'}(t+1|k) - \hat{x}^{u(u'v')}(t+1|t) \right]$$
(A.38)

$$P^{u(u'v')}(t|k) = P^{u}(t|t) + A \left[ P^{u'v}(t+1|k) - P^{u(u'v')}(t+1|t) \right] A^{T}$$
(A.39)

where  $A = P^{u}(t|t) \{F^{v'}(t+1,t+\delta) \ R \ F^{u'}(t+\delta,t)\}^{T} \ [P^{u(u'v')}(t+1|t)]^{-1}$ . Further the terms  $\hat{x}^{uv}(t+1|t)$  and  $P^{uv}(t+1|t)$  can be derived as

$$\hat{x}^{u(u'v')}(t+1|t) = F^{v'}(t+1,t+\delta) \ R \ F^{u'}(t+\delta,t) \ \hat{x}^{u}(t|t)$$
(A.40)

$$P^{u(u'v')}(t+1|t) = F^{v'}(t+1,t+\delta) R \left[ F^{u'}(t+\delta,t) P^{u}(t|t) F^{u'}(t+\delta,t)^T + Q^{u'}(t+\delta,t) \right] R^T F^{v'}(t+1,t+\delta)^T + Q^{v'}(t+\delta,t+1)$$
(A.41)
