#### ABSTRACT

Nitric oxide has been implicated in a number of biological processes, the majority of them involving iron nitrosyl complexes. The urgency then is to further study and characterize these complexes to further the understanding of biological mechanisms. However, the chemical sensitivity of these species precludes the purification and isolation of these compounds which, unfortunately, has directed the trend to merely detecting the presence of these compounds rather than isolating them. To this day, a large number of Electron Paramagnetic Resonance (EPR) detectable, biological compounds have not been isolated.

To this end, the series of biologically relevant compounds of the form  $Fe(NO)_2(L)_2$ [ L = imidazole 1, 1-methylimidazole (1-MeIm) 2, 4-methylimidazole (4-MeIm) 3, benzimidazole (benzim) 4, and 5,6-dimethylbenzimidazole (56benzim) 5 ] have been synthesized by direct reaction of the appropriate imidazole ligand with  $Fe(NO)_2(CO)_2$ . The compounds were extremely air sensitive, both in solution and as a dry solid. This hindered attempts to purify these compounds and so, infra red (IR), nuclear magnetic resonance (NMR) and EPR spectroscopic studies were undertaken of 2:1 reaction mixtures of the appropriate imidazole ligand and  $Fe(NO)_2(CO)_2$ . These studies revealed that the rapid substitution of the carbonyl ligands is facilitated by a catalytic, 17-electron, electron transfer chain mechanism (ETC), where the imidazole ligand acts to oxidize the 18-electron complex into the active 17-electron  $Fe(NO)_2(CO)_2^+$  species.

In the course of the EPR study of **2**, crystals formed that were suitable for singlecrystal, X-ray diffraction. The compound crystallizes with a monoclinic unit cell, in the C2/c space group with unit cell dimensions: a = 13.985(5) Å, b = 11.529(5) Å, c = 15.471(4) Å,  $\alpha = 90^{\circ}$ ,  $\beta = 91.72(2)^{\circ}$ ,  $\gamma = 90^{\circ}$ , V = 2493(2) Å<sup>3</sup>, Z = 8. During the course of study of 6, crystals suitable for single crystal X-ray diffraction were obtained. The compound crystalizes with a monoclinic unit cell, in the P2/c space group and unit cell dimensions: a = 11.707(9)Å, b = 8.1783(5) Å, c = 17.2489(13) Å,  $\alpha = 90^{\circ}$ ,  $\beta = 106.562(1)^{\circ}$ ,  $\gamma = 90^{\circ}$ , V = 1583.0(2)Å<sup>3</sup>, Z = 2.

A relatively new mass spectrometry (MS) procedure was utilized for the reaction mixtures of 1 - 5, which involved a combination of electrochemical oxidation and electrospray. The method proved very useful, yielding data that could not be obtained by other MS techniques. Oligomeric species of the form L-[(Fe(NO)<sub>2</sub>L]<sub>x</sub> (x = 2,3,4,5 or 6), were also detected by MS for each compound reaction mixture. The oligomers involved linear chains of iron dinitrosyl fragments linked via the imidazole nitrogens. However, it is believed that these oligomers are produced as a result of the conditions met by the mass spectrometer.

A reaction of  $Fe(NO)_2(PPh_3)(CO)$  with 1-MeIm was also performed in hopes of producing a more stable mono-substituted complex. However, the reaction also proceeded via an Electron Transfer Chain (ETC) pathway to produce  $Fe(NO)_2(PPh_3)_2$  6.

### ACKNOWLEDGEMENTS

I would like to thank my supervisor, Dr. Lijuan Li for her guidance and patience over the past couple of years. It was an interesting experience starting up a lab.

I would like to thank my coworkers: Guodong Zheng, Roger Liu and especially Nada Reginato who made the lab a fun place to work.

Thanks go to Dr. Donald Hughes and Mr. Brian Sayer for the NMR time and advice, and to George Timmins for the IR and EPR help. Thanks also to Dr. Jim Britten and Mark Stradiotto for their time and advice for X-ray crystallography work.

I would also like to thank Randy, Pippa and Buck and the rest of the Pheonix all stars, with whom I have achieved critical mass on numerous occasions.

Finally, I would like to thank my parents and my brother Ian for their love, support and guidance over the years. I need no other role models.

# **1. Introduction**

It is well known that the earth's atmosphere functions as a an insulating, thermal barrier, much like a greenhouse, and in doing so, provides the warmth necessary for the persistence of life on earth. The destruction of the "natural" protective atmosphere arises from four sources a) increased production of greenhouse gases such as the type of formula  $NO_x$ , b) increase in acidity of natural rain by nitrogen and sulfur oxides, c) depletion of the protective ozone layer by radical nitrogen oxide species, d) increased levels of secondary pollutants such as peroxyacetyl nitrate (PAN). Figure 1.1 shows the cycle that gives rise to

Figure 1.1. The NO/NO<sub>2</sub> removal processes in the troposphere

these concerns with regards to NO<sub>x</sub> in the troposphere.

Naturally occurring nitrogen oxides (NO<sub>x</sub>) originate from forest regions, marshlands, and grasslands. Other "natural" sources of NO<sub>x</sub> are derived from forest fires, and lightning where the temperature may reach upwards of 30,000 K.<sup>1</sup> Nearly all of the anthropogenic  $NO_x$  production occurs as a result of high temperature combustion devices, *via* the oxidation of  $N_2$  or organic nitrogen compounds. Indeed, it is the brown colour of gaseous  $NO_2$  that helps contribute to haze associated with smog-induced low visibility in industrialized cities.

The nitric oxide gases are known to cause respiratory problems, while PAN causes eye irritation. Nitrogen dioxide (NO<sub>2</sub>) initiates lipid oxidation in biological systems, and its inhalation has been associated with the biosynthesis of carcinogenic nitrosamines. Also, nitrogen oxides have been found to stimulate the nitration of polycyclic aromatic hydrocarbons *in vivo* to produce complexes that display mutagenicity, genotoxicity and carcinogenicity.<sup>2</sup>

However, despite the increasing environmental concern over nitric oxide gases and toxicological health issues, the nitric oxide (NO) molecule has been found to be one of the most important biological molecules ever discovered and has recently been named molecule of the decade.<sup>3</sup> This discovery has lead researchers to aggressively pursue the little known life of NO in living systems.

#### **1.2 The Role of Nitric Oxide in Living Systems**

The biological activity related to nitric oxide can be divided into two areas, indirect and direct effects. The principal reason that the chemical biology of NO can be partitioned in this manner is because NO has the capacity to react with molecules either directly, or as a pre-formed derivative or a metal complex.

## 1.2.1 Indirect effects of NO

The association of NO with stimulation of cyclic guanosine monophosphate (cGMP) production consequently links NO with a variety of physiological effects.<sup>4</sup> Cyclic GMP can act directly on ion channels and activate protein kinases, which catalyse the phosphorylation or dephosphorylation of proteins.<sup>4</sup> Furthermore, cyclic GMP directly regulates membrane cation channels in retinal photoreceptor cells, mediates smooth muscle relaxation, inhibits platelet aggregation, modulates excretion of Na<sup>+</sup> by the kidney, and helps to regulate cardiac function by modulating Ca<sup>2+</sup> currents.<sup>5</sup> Sodium nitroprusside, Na<sub>2</sub>[NO(CN)<sub>5</sub>Fe]·2H<sub>2</sub>O, which has been marketed as Nipride,<sup>5</sup> is often used to lower blood pressure in humans. Its hypotensive effect is evident within seconds after infusion, and the desired blood pressure is usually obtained in 1-2 minutes. Other nitrosyl compounds such as K[NOBr<sub>5</sub>Ir], K<sub>2</sub>[NOCl<sub>5</sub>Ru] and [NO(NH<sub>3</sub>)<sub>5</sub>Ru]Cl<sub>3</sub> have also shown vasodilatory activity, presumably by releasing NO, but are too toxic for clinical use.

NO plays an important role as a messenger between neurons at synapses in the central nervous system,<sup>3</sup> where it acts as a diffusable, short lived molecule within a local space to help shape the three dimensional network of synaptic responses. It now appears that NO, functioning as a neuromodulator in the hippocampus of the brain plays a fundamental role in the basic neuronal processes that initiate learning and experience.<sup>4</sup>

Nitric oxide is produced by macrophages to kill both invasive cells and in the rejection of tissue grafts.<sup>5</sup> The toxic effect appears to come from inhibition of enzyme activity through nitric oxide bonding to non-heme iron-centers in proteins such as ribonucleotide reductase, and release of intracellular iron from the cells targeted by the

macrophages.

#### **1.2.2 Direct Effects of NO**

Nitric oxide exists as a persistent, stable radical. However, NO does not rapidly react with most biological substances in a manner analogous to oxygen radicals such as ·OH. Since the lifetime of NO *in vivo* is relatively short (less than 10 sec) only the faster direct reaction of NO, such as with metal centers or other radicals, proves to be important. Reactions with metal centers, mainly iron, are crucial to understanding the bioregulatory behaviour of NO.

Another important direct reaction of metal centers with NO is seen with cytochrome P450. Studies have shown the NO inhibits mammalian P450, which is thought to regulate hormone metabolism and, under infectious conditions, decrease drug metabolism in the liver. The inhibitory mechanism relies on formation of an Fe-NO bond formation which prevents the binding of oxygen, similar to the mechanism for CO inhibition.

Metalloproteins play a major role in controlling concentrations of nitric oxide *in vivo*. Nitric oxide reacts directly with oxyhemoglobin (HbO<sub>2</sub>) or oxymyoglobin to form nitrate and methemoglobin (MetHb) or metmyoglobin,<sup>6</sup> which reduces the intracellular concentrations of NO.

The reaction of heme proteins with NO is also important to understanding the mechanism for protection against reactive species in the body. Peroxides are thought to enter a cell and react with heme proteins to form ferryl (Fe=O) heme complexes. The ferryl heme

protein is then proposed to decompose and generate superoxide anion  $O_2^{-}$  and release the iron complex. The iron complex can further react with peroxides to generate very potent oxidants such as  $HO_2^{-}$  and  $H_2O_2^{-}$ . NO reacts with the iron complex, which results in the formation of methemoglobin<sup>6</sup> and inhibits the formation of oxidants.

One of the first clues that the immune system utilizes NO to combat pathogens came from electron paramagnetic resonance (EPR) studies in cells showing the formation of  $Cys_2Fe(NO)_2$ .<sup>7</sup> It has been proposed that NO may react directly with ferrodoxin proteins such as aconitase, an enzyme containing a 4Fe-4S cluster that catalyses the isomerization of citrate to isocitrate in the citric acid cycle, destroying the iron-sulfur cluster which results in the loss of enzymatic activity.

## **1.3 Structure and Bonding in Metal Nitrosyl Complexes**

The bonding in transition metal carbonyl or nitrosyl complexes may be considered to be made up of two components: (a) donation of electron density from a  $\sigma$ -type orbital on CO or NO onto the metal, and (b) a donation of electron density from the occupied metal *d*-orbitals into the  $\pi^*$  antibonding orbitals of the NO or CO ligand. The bonding picture described in Figure 1.2 applies to both nitrosyl and carbonyl bonding interactions. However, there are significant differences in the nature of the electron distributions in the M-NO and M-CO units. One difference stems from the fact that the nitrogen of NO is more electronegative than the carbon of CO,<sup>8</sup> the result being that the NO ligand is a better overall electron acceptor than CO. Another important difference is that in the M-NO unit, the M-N

Figure 1.2. Molecular Bonding diagram for Metal Nitrosyls

bond is usually strong, and the N-O bond is relatively weak; for carbonyls, the reverse trend is observed. The end result is that the M-N bond is strengthened and shortened by the backdonation while the addition of electron density to the antibonding  $\pi^*$  orbital weakens and lengthens the NO bond. In general, NO is considered to be a weak  $\sigma$ -donor and a strong  $\pi$ acceptor.

The nitrosyl group can bond to transition metals in a variety of ways, resulting in different geometries about the N atom. One method used to describe the bonding of nitrosyl compounds (the method used in this thesis) is to assign formal oxidation states to the metal and the nitrosyl ligand.<sup>8</sup> With this assignment, a linear M-NO (Figure 1.3 A) unit would occur as the result of a bound NO<sup>+</sup> ligand (which is isoelectronic with CO and N<sub>2</sub>). Coordination of nitric oxide as NO<sup>+</sup> involves a net donation of three electrons from NO to a metal atom. The extra electron is considered to be in the *d* set of orbitals of iron, giving rise to an oxidation state of -2 for Fe(NO)<sub>2</sub>(L)<sub>2</sub> complexes. A bent M-NO (Figure 1.3 B) unit would be the result of a bound NO<sup>-</sup> ligand. Coordination as NO<sup>-</sup> involves a net donation of

one electron to the metal.

**Figure 1.3.** Nitrosyl Bending in Metal complexes. A: Linear "3 electron" bonding. B: Bent "1 electron bonding"

# 1.4 The Chemistry of Metal Nitrosyl Complexes

#### **1.4.1 Formation of Metal Nitrosyls**

There are a number of ways in which iron nitrosyl complexes are prepared. The earlier syntheses involved the combination of aqueous solutions of Fe(II) salts, anionic ligands and a source of NO gas.<sup>9</sup> These methods produced useful EPR results, but the shortcoming of this earlier work was that isolation and purification of the compounds was not accomplished.

The most successful formation of metal nitrosyl complexes is by displacement of ligands in the coordination sphere of a metal. Again, this can be accomplished by using NO gas to displace a ligand equivalent to that of a 3-electron donor.<sup>10</sup> Nitric oxide gas can also displace two-electron ligands in some monometallic compounds, with subsequent formation of a bimetallic species (presumably because of the extra electron afforded by NO); it can also add to a bi- or polymetallic complex with the subsequent cleavage of metal-metal bonds.<sup>11</sup>

Nitrosonium salts have also been used for the synthesis of metal nitrosyls. NO<sup>+</sup> forms simple 1:1 adducts with some coordinatively unsaturated metal complexes (Equation 1).<sup>12</sup>

$$Ir(CO)ClL_2 + NO^+ \rightarrow [Ir(NO)(CO)ClL_2]^+$$
 (1)

 $NO^+$  also readily displaces CO (or other 2-electron ligands such as carbon disulfide) in a number of coordinatively saturated complexes to generate their nitrosyl analogues (eq 2, 3),<sup>12</sup>

$$CpMn(CO)_{3} + NO^{+} \rightarrow [CpMn(NO)(CO)_{2}]^{+} + CO \quad (2)$$
  
Fe(CO)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>(CS<sub>2</sub>) + NO<sup>+</sup> \rightarrow [Fe(CO)\_{2}(PPh\_{3})\_{2}NO]^{+} + CS\_{2} \quad (3)

and a variety of nitrosyl halides have been used extensively in formation of metal complexes.<sup>13</sup>

Inorganic nitrites have also been used to obtain metal nitrosyl complexes. The most common nitrite sources for the synthesis of monometallic and cluster complexes are  $PPN(NO)_2$  and sodium nitrite (eq 4, 5).

$$Cr(CO)_6 + PPN(NO_2) \rightarrow PPN[Cr(NO)(CO)_4]$$
 (4)  
 $Ru(CO)_5 + PPN(NO_2) \rightarrow PPN[Ru(NO)(CO)_3]$  (5)

The fact that, in acidic media, the nitrite ion equilibrates with the  $NO^+$  cation has been exploited (6) for nitrosylation (7, 8).

$$NO_2^- + 2H^+ \Rightarrow H_2O + NO^+$$
 (6)

$$[Ru(bipy)_2(H_2O)Cl]^+ + NO_2^- \rightarrow No reaction (7)$$

$$[\operatorname{Ru}(\operatorname{bipy})_2(\operatorname{H}_2O)\operatorname{CI}]^+ + \operatorname{NO}_2^-/\operatorname{H}^+ \rightarrow [\operatorname{Ru}(\operatorname{NO})(\operatorname{bipy})_2\operatorname{CI}]^{2+} (8)$$

Other metal nitrosylation reactions have been accomplished by reactions with azides, organic nitroso ligands, hydroxylamine and protonation of aminato-type ligands.<sup>12</sup>

## **1.4.2 The Reactivity of Metal Nitrosyls**

The M-NO moiety exhibits a wide range of reactivity, including simple conformational changes and reactions at the N and O atoms. In simplistically viewing the linear NO ligand as an electrophile (formally NO<sup>+</sup>), it should be rendered prone to nucleophilic attack at the nitrosyl nitrogen. Conversely, the bent NO ligand (formally NO<sup>-</sup>) should undergo electrophilic attack at the nitrogen atom. The NO groups can also serve as "spectator" ligands, while still conferring unique chemical reactivity to metal centers.

In solution, a number of compounds have shown the ability to convert from linear to bent conformations. For example, the five coordinate  $[RuCl(NO)_2(PPh_3)_2]BF_4$  complex possesses both linear and bent ligands in the solid state but is fluxional in solution due to a rapid, intramolecular interconversion.<sup>14</sup>

The compound  $[Ir(NO)(\eta^3-C_3H_5)(PPh_3)_2]^+$  (Figure 1.4) in solution also shows a linear-bent NO interchange,<sup>15</sup> in the absence of interchange occurs without an accompanying  $\eta^3-\eta^1$  allyl fluxional process. Both linear and bent nitrosyl forms of the complex have been crystallized as their PF<sub>6</sub><sup>-</sup> and BF<sub>4</sub><sup>-</sup> salts.

Figure 1.4 Linear-bent interchange of  $[Ir(NO)(\eta^3-C_3H_5)(PPh_3)_2]^+$ .

The linear-to-bent NO conformational changes may be induced chemically by the

Figure 1.5. Linear-bent interchange by chemical addition.

addition of neutral or anionic nucleophiles (L) to the metal center as shown in Figure 1.5. For example,  $[Co(NO)(das)_2]^{2+}$  (das = O-phenlyenebis(dimethyl)arsine) has a linear (179°) nitrosyl. Addition of thiocyanide to this complex gives rise to  $[Co(NO)(das)_2(NCS)]^{2+}$  with a bent nitrosyl (132°).<sup>16</sup>

Lewis acids such as AlMe<sub>3</sub>, Cp<sub>3</sub>Er and Cp<sub>3</sub>Yb can react with the oxygen of nitrosyls, forming the corresponding adducts.<sup>17,18</sup> When the Lewis acid binds with the nitrosyl oxygen, electron density is drained away from the NO group, and the metal compensates by donating more electron density into the  $\pi^*$  orbitals of NO. Thus, the v<sub>NO</sub> is lowered, by an amount determined by the strength of the interaction between the NO ligand and the lewis acid.

The oxygen of the NO ligand can also be removed by oxygen acceptors (eq 9).<sup>19</sup>

$$[\text{FeRu}_{3}(\text{NO})(\text{CO})_{12}]^{-} \longrightarrow [\text{FeRu}_{3}(\text{N})(\text{CO})_{12}]^{-} + \text{CO}_{2} \quad (9)$$

If the MNO group is sufficiently electron rich, it may undergo electrophilic attack by protons. The bent NO is formally  $sp^2$  hybridized and possesses a lone pair of electrons (eq 10, 11).<sup>20</sup>

$$Os(NO)Cl(CO)(PPh_3)_2 + HCl \rightarrow Os(HNO)Cl_2(CO)(PPh_3)_2 \quad (10)$$
  
Re(NO)<sub>2</sub>(PPh\_3)<sub>2</sub>(I) + HCl \rightarrow Re(NO)(HNO)(PPh\_3)\_2Cl(I) \quad (11)

Nucleophiles can react with the nitrogen of NO if the M-NO unit is essentially linear. It has been proposed <sup>21</sup> that addition of hydride anion to  $[CpRe(NO)(CO)(PPh_3)]^+$  results in the formation of a formyl complex *via* an HNO intermediate, which isomerizes to the formyl product as shown in Figure 1.6.

Figure 1.6. Reaction of a nucleophile with the nitrogen of NO.

Similarly, the reaction of a cobalt dinitrosyl complex with borohydride leads to reduction of the NO ligand and the formation of ammonia (12).<sup>22</sup>

$$[Co(NO)_2(PPh_3)_2 \xrightarrow{BH_4^2} Co(NO)(PPh_3)_3 + NH_3$$
(12)

#### 1.4.3 Irondinitrosyldicarbonyl

The formation of a volatile iron nitrosyl-carbonyl was first observed by Mond and Wallis.<sup>23</sup> It is a deep red compound, with a melting point of 18.4 °C and a density of 1.56 g.cm<sup>-3</sup>. Fe(NO)<sub>2</sub>(CO)<sub>2</sub> is diamagnetic, having a filled  $d^{10}$  shell. It is insoluble in water but

very soluble in organic solvents. The liquid starts decomposing at 50 °C,<sup>24</sup> leading to Fe<sub>2</sub>O<sub>3</sub> and other products. Fe(NO)<sub>2</sub>(CO)<sub>2</sub> is unstable in air and decomposes slowly at room temperature by oxidation. With NaOH or NaOCH<sub>3</sub> in CH<sub>3</sub>OH disproportionation of Fe occurs yielding [Fe(CO)<sub>3</sub>NO]<sup>-</sup> and [Fe(CH<sub>3</sub>OH)<sub>5</sub>NO]<sup>2+</sup>, CO and NO<sup>-</sup>. The Formation of Fe(NO)<sub>2</sub>(CO)<sub>2</sub> by Fe(CO)<sub>5</sub> and nitrite is shown in Scheme 1.1. The reaction takes place initially in methanol. At step 1 in the scheme, Na[Fe(CO)<sub>3</sub>NO] is formed. The methanol is distilled off and the salt dried, at which point water and more nitrite is added to the salt, and the resulting slurry is acidified with CO<sub>2</sub> to produce the starting material **2** in the scheme.

The geometry of the iron centre is reflected in the nature of the ligands attached.<sup>25</sup> For example, the Fe(NO)<sub>2</sub> unit has a large angle for N-Fe-N. The configuration develops because a better  $\pi$  overlap between the Fe and N orbitals is achieved at wider angles. In general, strong  $\pi$ -acids (L) will necessarily have a large L-Fe-L angle. Conversely, the much weaker $\pi$ -acids, such as Cl-, will have a smaller L-Fe-L angle. The poor  $\pi$ -acceptors rely mainly on  $\sigma$  interactions, which operate at more acute angles. The geometry can also be reflected in the electronic configuration of the iron center. The oxidation of the  $d^{10}$  Fe(NO)<sub>2</sub> complex to  $d^9$  causes geometric distortions,<sup>26</sup> involving a change in shape from tetrahedral to more of a trigonal pyramid, with a missing ligand at the apex. The single electron is occupied in the  $d_z^2$  orbital, which pushes the ligands down. The change from  $d^9$  to  $d^8$  further distorts the four coordinate complex towards a square planar conformation.<sup>25</sup> The  $Fe(NO)_2(L)_2$  [L = PR<sub>3</sub>, NR<sub>3</sub>] compounds formed by reaction of  $Fe(NO)_2(CO)_2$  and L have been shown to proceed by a conventional associative mechanism.<sup>27</sup> The conventional process is slow, requiring stirring overnight to replace the first carbonyl and requiring heating at 85°C overnight to replace the second carbonyl.<sup>28</sup> A number of Fe(NO)<sub>2</sub>(X)<sub>2</sub> [X

Scheme 1.1. Proposed mechanism of formation of Fe(NO)<sub>2</sub>(CO)<sub>2</sub>.

=  $PR_3$ ,]<sup>29</sup>and [Fe(NO)<sub>2</sub>(CO)]<sub>2</sub>Y [Y = dppe or dppm<sup>30</sup>] compounds have been previously synthesized, and the ortep diagrams of [Fe(NO)<sub>2</sub>(CO)]<sub>2</sub>dppe and dppm are shown in Figures 1.7 and 1.8, respectively. Each iron is situated in a pseudo-tetrahedral environment.

#### **1.5 Research Objectives**

Nitric oxide's rapid reactivity with oxygen and other substances in water suggests that, in some instances, NO transport may be affected by metal ion complexation. The trend has been to detect the presence of these compounds rather than isolate them. To this day, a large number of biologically detectable EPR compounds have not been isolated. In fact, the majority of compounds made are made with P and S ligands, and a number of reviews describing these compounds are in the literature.<sup>31,32</sup> It has been our goal to synthesize and fully characterize a series of non-heme, non sulfur iron dinitrosyl compounds, an area of synthesis which has not previously attracted much attention. We focussed on the synthesis of biologically relevant compounds that mimic histidine iron compounds, by using a series of imidazoles (histidine is an imidazole containing amino acid), including imidazole, 1methylimidazole, 4-methylimidazole, benzimidazole, and 5,6-dimethylbenzimidazole. These were reacted with dinitrosyldicarbonyliron to form disubstituted complexes of the form  $Fe(NO)_2(L)_2$  [ L = imidazole 1, 1-methylimidazole 2, 4-methylimidazole 3, benzimidazole 4, and 5,6-dimethylbenzimidazole 5]. We emphasized characterization of 1-5 by IR, Mass spectrometry, NMR and X-ray crystallography. EPR studies are compared with previous EPR studies of biological iron dinitrosyl mimics.

# 2. Results and Discussion

## 2.1 Mechanism of Reaction of iron dinitrosyl compounds with imidazole ligands.

Synthesis of the  $Fe(NO)_2(L)_2$  [L = imidazole 1, 1-methylimidazole 2, 4methylimidazole 3, benzimidazole 4, 5,6-dimethylbenzimidazole 5] series of compounds were carried out under inert atmosphere, utilizing rigorously dried and degassed solvents. The reaction mixtures consisted of a 2:1 molar ratio of the appropriate imidazole ligand with a solution of  $Fe(NO)_2(CO)_2$  dissolved in THF, ether, or dichloromethane. Upon addition of ligand, the solution turned from red to green withing two minutes, with fierce gas evolution. As well, an EPR detectable signal was observed for each reaction mixture of 1 - 5. These observations indicate that the reaction rate is much greater than that of conventional substitution and therefore the mechanism of substitution proceeds by a pathway other than that of conventional associative substitution.

To determine the mechanism of reaction, attention must first be focussed on the formation of an EPR detectable species in each reaction mixture. The signal, centered approximately at g = 2.03G, is consistent with a 17 electron complex that has the unpaired electron situated mainly on iron. A 19 electron complex is ruled out, as these complexes typically have isotropic g-factor values < 2.000G.

A variety of 17 electron complexes have been previously studied.<sup>33</sup> For example, the complex  $[(MeCp)Mn(CO)_3]$ , while normally inert to CO substitution (it does not react

thermally with PPh<sub>3</sub> over 3 days at 140  $^{\circ}$ C), does undergo substitution of one or two CO

Scheme 2.1. Enhanced rate of CO substitution by oxidation of  $[(MeCp)Mn(CO)_3]$  to the 17 electron  $[(MeCp)Mn(CO)_3]^+$  intermediate.

ligands within milliseconds at room temperature upon oxidation in the presence of  $P(OEt)_{3}$ .<sup>34</sup> The chemistry involved is illustrated in Scheme 2.1. Kochi and co-workers<sup>35,36</sup> have established that rapid ligand substitution occurs when a slight oxidizing current is applied (or a small amount of a chemical oxidizing agent is added) to a MeCN solution of  $[(MeCp)Mn(CO)_2(MeCN)]$ . The electrochemical investigation showed that the reaction occurs by a "catalytic electron-transfer chain process"<sup>35</sup> (ETC) defined in Scheme 2.2. The catalytic cycle is initiated by oxidation of a small amount of reactant [Mn-NCMe] to yield the 17 electron [Mn-NCMe]<sup>+</sup>, which rapidly substitutes PR<sub>3</sub> for MeCN to give [Mn-L]<sup>+</sup>. It happens that the reactant [Mn-NCMe] is more easily oxidized than is the product [Mn-L], which ensures that [Mn-NCMe]<sup>+</sup> is continuously regenerated by electron transfer from [Mn-NCMe] to [Mn-L]<sup>+</sup>.

Another such reaction is that of Fe(NO)<sub>2</sub>(CO)(PPh<sub>3</sub>) with TCNE (Scheme 2.3) as

**Scheme 2.2.** Enhanced rate of CO substitution by oxidation of [(MeCp)Mn(CO)<sub>2</sub>(MeCN)] to the 17 electron [Mn-NCMe]<sup>+</sup> intermediate .

reported by Li and coworkers.<sup>37</sup> Generally substitution of one CO of Fe(NO)<sub>2</sub>(CO)<sub>2</sub> usually calls for overnight stirring and replacing the second carbonyl requires heating to 85 °C for 16 h.<sup>38</sup> However, substitution of CO by TCNE was complete in 1-2 h.<sup>37</sup> The reaction was monitored by EPR and both TCNE<sup>-</sup> and Fe(NO)<sub>2</sub>(PPh<sub>3</sub>)(L)<sup>+</sup> radicals were observed (L may be CO or solvent). They suggested that a "radical mechanism involving a 17-electron intermediate", as shown in Scheme 3, was responsible for the enhancement of the rate of substitution without the use of an oxidizing agent such as Co(cp)<sub>2</sub>, or an oxidizing potential. The TCNE ligand acts both as the oxidizing agent, and as the ligand to replace CO. Indeed, it has been shown that the reaction of [Fe(NO)<sub>2</sub>CO]<sub>2</sub>dppe with TCNE also produces TCNE<sup>-</sup> in solution, and the mechanism proceeds *via* a 17-electron intermediate described in Scheme

With no apparent added source of oxidizing agent, and no applied oxidizing current,

**Scheme 2.3**. Enhanced rate of CO substitution *via* oxidation of  $Fe(NO)_2(CO)(PPh_3)$  to  $Fe(NO)_2(CO)(PPh_3)^+$  by TCNE.

the formation of compounds **1** - **5** proceed *via* a 17 electron ETC pathway similar to that of Li. Scheme 2.4 describes the mechanistic pathway associated with the ETC substitution of CO by the series of imidazole ligands. The first run through will produce the mono-substituted  $Fe(NO)_2(CO)(L)$  complex, a compound which had been detected previously<sup>39</sup> by IR spectroscopy during reaction of  $Fe(NO)_2(CO)_2$  and 1-MeIm. A second run through of the cycle, replacing  $Fe(NO)_2(CO)_2$  with  $Fe(NO)_2(CO)(L)$  results in the di-substituted product. However, the proposed mechanism involves the formation of an Im<sup>-</sup> compound, which has not been detected by EPR.

The final product was chemically sensitive to a variety of conditions. In air it

immediately turned from the characteristic green colour of the Fe(NO)<sub>2</sub>(L)<sub>2</sub> complex to a clear brown solution, and further, to a clear solution with an orange precipitate within 7-10 minutes. Removal of solvent by reduced pressure afforded a green solid. Non-polar solvents such as ether and paraffin oil did not dissolve the product, however, the supernatant solution acquired a slight brownish tinge. The green solid did dissolve in chloroform and dichloromethane and created a clear brown solution that did not show precipitation after several days. NMR spectroscopy of deuterated chloroform solutions revealed extremely broadened lines, but nothing discernable. Methanol dissolved the green solid and retained the distinctive green colour in solution, however, this was short lived and the solution turned brown after 30 minutes. NMR spectroscopy of deuterated MeOH solutions also produced spectra with very broadened lines which could not be interpreted. The instability of these complexes may be due to the inability of the poor  $\pi$ -accepting ability of the imidazole ligands to stabilize the lower oxidation state of iron.<sup>40</sup>

In an effort to try to stabilize the final products, the compound  $Fe(NO)_2(CO)(PPh_3)$  was used, with the strong  $\pi$ -accepting PPh<sub>3</sub> ligand as a stabilizer. Iron dinitrosyl products with a PR<sub>3</sub> ligand are relatively more stable as a solid than the starting material,  $Fe(NO)_2(CO)_2$ , and it was hoped that this ligand would increase the stability of a monosubstituted imidazole compound. Addition of 1-MeIm to a solution of Fe(NO)<sub>2</sub>(CO)(PPh<sub>3</sub>)

produced violent gas evolution, and a darkening of the solution from red to a very dark red/green colour, which had been observed in the formation of complexes 1-5. Crystals were obtained which revealed  $Fe(NO)_2(PPh_3)_2$  (6). This result was not expected, however it is easily explained using a variation of the mechanism shown in Scheme 2.4. Scheme 2.5 details the ETC pathway for formation of 6. The first time through the cycle, both  $Fe(NO)_2(PPh_3)(Im)$  and  $Fe(NO)_2(CO)(Im)$  are produced. The formation of Fe(NO)\_2(CO)(Im) releases free PPh<sub>3</sub> into solution which, after a second run through the cycle, can react with  $Fe(NO)_2(PPh_3)(Im)$  to give 6.

Scheme 2.4. Mechanistic pathway for formation of the  $Fe(NO)_2(L)_2$  [L = imidazole, 1-MeIm, 4-MeIm, Benzim, 5,6-dimethylbenzim] series of compounds.

Scheme 2.5. Mechanistic pathway for formation of the  $Fe(NO)_2(L)_2$  [L = PPh<sub>3</sub>] from the reaction of  $Fe(NO)_2(CO)(PPh_3)$  and 1-MeIm.

## **2.2 Infrared Spectroscopy**

While the MNO group is expected to exhibit  $v_{NO}$ ,  $v_{MN}$  and  $v_{MNO}$ , only  $v_{NO}$  has been identified in most cases in the vibrational spectra of metal nitrosyl complexes.<sup>41</sup> In most nitrosyl complexes, the N-O stretching frequency is observed as an intense and characteristic band in the region 1525-1940 cm<sup>-1</sup>, which is associated with monodentate nitrosyl groups. Assuming the nitrosonium coordination model, the free NO<sup>+</sup> stretching of 2250 cm<sup>-1</sup> would be expected to drop on coordination with a metal atom. This is caused by the increase in back donation of electron density from M to NO and population of the  $\pi^*$  orbital, which weakens the N-O bond. Conversely, a net donation of electron density from the NO group to the metal center should result in a stronger N-O bond, and hence a higher  $\nu_{\text{NO}}$  . The magnitude of this decrease depends on the nature of the metal atom and the degree of  $\sigma$ - and  $\pi$ - bonding involved. This simplistic view is useful when monitoring the progress of a chemical reaction. Linear M-N-O groups absorb in the region 1650-1940 cm<sup>-1</sup>, including M-N-O angles from 160 to 180°, for which the NO ligand has a formal positive charge. The stretches for the bent groups (M-N-O angle 120°) occur at lower wavenumbers (1525-1690 cm<sup>-1</sup>).<sup>42</sup>

Fe(NO)<sub>2</sub>(CO)<sub>2</sub> have intense stretching frequencies for both NO (1810, 1767 cm<sup>-1</sup>) and CO (2087, 2038 cm<sup>-1</sup>). Upon addition of the imidazole ligands, the  $v_{NO}$ 's are lowered by approximately 140 wavenumbers and no carbonyl stretching frequencies are observed. This indicated that two Im ligands had replaced the two CO ligands. The nitrosyls fall into the region of 1650-1940cm<sup>-1</sup>, indicating they are linear. Table 2.1 lists the NO stretching frequencies observed for complexes **1 - 5**.

Compound	v <sub>NO</sub> (cm <sup>-1</sup> )
1 $Fe(NO)_2(imidazole)_2$	1680, 1622
2 $Fe(NO)_2(1-MeIm)_2$	1673, 1616
3 $Fe(NO)_2(4-MeIm)_2$	1677, 1620
4 $Fe(NO)_2(Benzimidazole)_2$	1682, 1625
5 $Fe(NO)_2(5,6-dimethylbenzim)_2$	1683, 1625

**Table 2.1** Nitrosyl stretching frequencies for compounds 1 - 5.

#### 2.3 Nuclear Magnetic Resonance Spectroscopy

Numbering Scheme for 1-MeIm

The solids of the  $Fe(NO)_2(L)_2$  [L = imidazole 1, 1-methylimidazole 2, 4methylimidazole 3, benzimidazole 4, 5,6-dimethylbenzimidazole 5] could not be purified by conventional means. The NMR spectroscopy was therefore carried out using reaction mixtures of the imidazole series of compounds in deuterated solvents, such as d-chloroform and *d*-methanol (the deuterated solvents were rigorously dried over CaH<sub>2</sub>). Analysis of the spectra proved difficult, as obvious line broadening occurred from paramagnetic species in solution. Repeated attempts produced only one spectrum, that of 2, which could be deciphered. The proton spectrum of 2, shown in Figure 2.1, reveals a mixture of 1-MeIm and Fe(NO)<sub>2</sub>(1-MeIm)<sub>2</sub> in solution. The broad signal at 8.79ppm is attributed to H2 and H4 of 2 (see 1-MeIm diagram above for numbering scheme). It is believed that the resonances of H2 and H4 are similar, and with line broadening, only one broad signal is observed. The 1-MeIm ligand act as an electron donor, and so the protons of H2 and H4 are deshielded upon complexation with the iron and are shifted further downfield with respect to the free 1-MeIm molecule. The signal at 4.99ppm is assigned to H5, which is not subjected to any deshielding by complexation. The broad peak at 3.97 ppm is assigned to the CH<sub>3</sub> group. The peaks at
7.68, 7.10, 6.87, and 3.68 ppm are assigned to H2, H4, H5, and  $CH_3$  of the free 1-MeIm ligand, respectively.

The <sup>13</sup>C spectrum, shown in Figure 2.2, also reveals a mixture of 1-MeIm and  $Fe(NO)_2(1-MeIm)_2$  in solution. The small signals at 226.2 and 225.6 ppm are attributed to either of the C2 and C4 carbons. Again, these atoms are affected by the deshielding which occurs upon complexation. Definitive assignment of these two atom resonances was not made. The peak at 143.4 ppm is assigned to the C5 carbon and the broad peak at 38.3 ppm is attributed to the CH<sub>3</sub> carbon. The resonance peaks at 143.6, 134.2, 123.1, and 34.2 ppm arise from the C2, C4, C5 and CH<sub>3</sub> carbons of the free 1-MeIm ligand, respectively.

## **2.4 EPR Spectroscopy**

Electron paramagnetic resonance spectroscopy (EPR) has been one of the most commonly employed techniques for the characterization of iron dinitrosyl complexes. Although solution EPR cannot be used to determine the geometry of complexes, the spectra are useful as a means of confirming the presence of the desired product. For example, Martini and co-workers<sup>42</sup> reported a study on a mixture of urea and an Fe(NO)<sub>2</sub> complex. Urea  $(H_2N-CO-NH_2)$  can be expected to bind through either its carbonyl oxygen atom, or one of the two nitrogen groups. The spectrum of  $Fe(NO)_2(urea)_2$  revealed a five line spectrum (g = 2.034,  $a_n = 2.2G$ ) which indicated the interaction of the unpaired electron with only two equivalent nuclei of <sup>14</sup>N of the nitrosyls. The urea molecules are therefore bound to the  $Fe(NO)_2^+$  group by the carbonyl oxygen. In a similar aqueous study with imidazole,<sup>43</sup> the spectrum obtained consisted of nine hyperfine components spaced about 2.5 G apart, and indicated a compound with two equivalent <sup>14</sup>N nuclei from the nitrosyl groups and two equivalent <sup>14</sup>N nuclei from the imidazole groups, each with the same hyperfine coupling constant.

In the course of study of  $Fe(NO)_2(CO)_2$  with imidazole ligands, neutral compounds of the form  $Fe(NO)_2(L)_2$  [L = imidazole 1, 1-methylimidazole 2, 4-methylimidazole 3, benzimidazole 4, 5,6-dimethylbenzimidazole 5] were expected to be produced. However, NMR characterization proved difficult because of extensive line broadening. This suggested that a paramagnetic species was present in solution. EPR studies did reveal that a paramagnetic species was present in solution, which is believed to be a 17 electron, iron dinitrosyl intermediate involved in the formation of the 18 electron,  $Fe(NO)_2(L)_2$  complex. The g-values and hyperfine coupling constants observed for compounds **1** - **5** are listed in Table 2.2. Spectra simulation have been performed and are consistent with experimental data. Figures 2.3-2.7 show the experimental (top) and simulated (bottom) spectra for each compound.

**Table 2.2.** g values and hyperfine coupling constants for  $Fe(NO)_2(L)_2^+$  compounds. The number in parentheses is the number of nuclei to which the coupling belongs.

Compound	g-value	a <sub>n</sub>
Fe(NO) <sub>2</sub> (imidazole) <sub>2</sub>	2.0344	3.3 (1), 2.4 (1),
		2.1 (2)
$Fe(NO)_2(1-MeIm)_2$	2.0275	2.9 (2), 2.6 (2)
$Fe(NO)_2(4-MeIm)_2$	2.0336	3.1 (1), 2.5 (1),
		2.2 (2)
Fe(NO) <sub>2</sub> (benzimidazole) <sub>2</sub>	2.0341	3.8 (1), 2.4 (1),
		1.9 (2)
$Fe(NO)_2(5,6-dimethylbenzim)_2$	2.0344	3.9 (1), 2.2 (2)

Compounds 1-5 are all centred around 2.03 G, which is typical for iron dinitrosyl radicals with an unpaired electron localized on Fe as discussed by Li and co-workers.<sup>44</sup> The EPR spectra of compound 1, displayed in figure 2.3, shows a signal at 2.0343 G, that consists of 10 lines. Simulation reveals that the signal arises from the two equivalent <sup>14</sup>N nuclei of the nitrosyl ligands with a hyperfine coupling constant of 2.1 G and two inequivalent <sup>14</sup>N nuclei from the imidazole ligands with a coupling constant of 3.2 and 2.4 G. This experiment was

carried out in tetrahydrofuran, whereas previous studies by Martini<sup>45</sup> were carried out in aqueous solution which affects the g-value. The nine line spectrum reported was not symmetric and obviously consisted of four nuclei that were not mutually equivalent as they have suggested. Simulations were not performed by Martini confirm the coupling constants. Compound 2, whose EPR spectrum is shown in Figure 2.4, produces a signal centred at 2.0275 G, and is comprised of nine lines. Simulation reveals two equivalent <sup>14</sup>N nuclei from the nitrosyl ligands and two equivalent 1-MeIm ligands with coupling constants of 2.6 and 2.9 G, respectively. Compound 3 (Figure 2.5) produces a 10 line spectrum centred at 2.0337 G. The spectrum contains two equivalent <sup>14</sup>N nitrosyl groups, with a coupling constant of 2.2 G, and two inequivalent 4-MeIm ligands with coupling constants of 3.1 and 2.5 G. The spectrum of compound 4, shown in Figure 2.6, is centred at 2.0341 G and consists of eleven lines. Simulation revealed a compound with two equivalent <sup>14</sup>N nuclei from the nitrosyls, with hyperfine coupling of 1.9 G and two inequivalent <sup>14</sup>N nuclei from the BenzIm groups with hyperfine coupling equal to 3.8 and 2.4 G. The EPR spectrum of 5, shown in Figure 2.7, was centred at 2.035 G and consisted of 9 lines. The simulation for this spectrum revealed that only three <sup>14</sup>N nuclei were producing the hyperfine interactions. Two equivalent nitrosyl groups gave rise to a coupling of 2.2 G, and only one <sup>14</sup>N nucleus produces a coupling of 3.9 G. The reaction mixture of  $Fe(NO)_2(CO)_2$  and 5,6-dimethylbenzimidazole was in a 1:2 ratio to facilitate the substitution of two carbonyls by the imidazole ligands. It is unknown as to why only one 5,6-dimethylbenzimidazole ligand was involved in substitution.

## 2.5 X-Ray Crystallography

Single crystals of 2 were obtained from ether solution. The crystals were placed in a petri dish containing dry paraffin oil. The oil had been dried over sodium metal and purged with nitrogen for one week prior to use. A single green crystal, 0.06 x 0.25 x 0.30mm was mounted on a glass fibre, with the paraffin oil as the adhesive. The X-ray crystal structure of 2, Fe(NO)<sub>2</sub>(1-methylimidazole)<sub>2</sub> is shown in Figure 2.8. It crystallized as a monoclinic system, with a space group of C2/c and with the following dimensions: a = 13.985(5) Å, b = 11.529 (5) Å, c = 15.471(4) Å,  $\alpha = 90^{\circ}$ ,  $\beta = 91.72(2)^{\circ}$ ,  $\gamma = 90^{\circ}$ , V = 2493(2) Å<sup>3</sup>, Z = 8.

The iron atom is situated in a *pseudo*-tetrahedral environment, with two coordinated NO groups attached through the nitrogen and two coordinated 1-methylimidazole ligands attached by the *sp*<sup>2</sup> hybridized nitrogen. The nitrosyls are linear, having angles of 167.5(3)° and 170.1(3)°. They are situated with an angle of 116.5° between N<sub>1</sub>-Fe-N<sub>2</sub>. The O<sub>1</sub>-Fe-O<sub>2</sub> angle is 107.3°, and so forms an "attracto" conformation where O-M-O < N-M-N. This is in accord with the proposal that for complexes with N-M-N bond angles of less than 130°, the two O atoms bend towards each other.<sup>46</sup> The angle between N<sub>3</sub>-Fe-N<sub>5</sub> is 91.20°. The nitrosyl groups are much better  $\pi$ -acceptors than the 1-MeIm ligands and will necessarily have a larger angle between them than the corresponding 1-MeIm ligands.<sup>47</sup>

Since the 1-MeIm ligand is a poorer  $\pi$ -acceptor than PR<sub>3</sub>, dppe or dppm, the imidazole complex would be expected to have shorter Fe-N(O) and longer N-O bond distances than the phosphorous complexes. The  $\pi$ -acidity of the P ligand would compete with the  $\pi$ -accepting ability of N(O) and would, in effect, cancel each other out. The imidazole complex would not be able to compete with the Fe-N(O) backbonding, resulting

in a shorter Fe-N(O) and longer N-O bond. Table 2.3 compares the bond distances of some iron dinitrosyl complexes. The dppe and dppm complexes follow this trend loosely, with somewhat longer Fe-N bonds and only slightly longer N-O bonds. The PPh<sub>3</sub> complex does not follow this trend, with bond distances similar to that of the 1-MeIm complex.

	$Fe(NO)_2(1-MeIm)_2$	[Fe(NO) <sub>2</sub> (CO)] <sub>2</sub> dppe	[Fe(NO) <sub>2</sub> (CO)] <sub>2</sub> dpp	$Fe(NO)_2(PPh_3)_2$
			m	
Fe-N (avg)	1.649	1.680	1.685	1.651
N-O (avg)	1.189	1.170	1.171	1.188

Table 2.3. Comparison of iron dinitrosyl bond lengths (in Å).

If a plane were to pass horizontally through each of the flat 1-MeIm ligands, the two planes would be skewed 106.7° from each other. The methyl groups on the N4 and N6 atoms 1-MeIm point to the same side of the molecule, bestowing close to a C<sub>s</sub> symmetry rather than a C<sub>2</sub> symmetry. A crystal packing diagram, shown in Figure 2.9, reveals a layering of 1-MeIm ligands (not to be confused with  $\pi$  stacking), a phenomenon previously encountered in iron dinitrosyl compounds.<sup>48</sup> Closer inspection shows that each of two H's of a methyl group is sandwiched between two nitrosyls, the two nitrosyls coming from different molecules. Each hydrogen is in close proximity with the oxygen of the NO ligands, which may prove to be a hydrogen bonding effect and a reason why the remaining four imidazole complexes do not readily form crystals. The third hydrogen of the methyl group is not involved in hydrogen bonding.

The crystal structure of **6** has been previously reported.<sup>49</sup> The unit cell dimensions for both refinements match, however, the quality of the data of the previous study is questionable. Firstly, the thermal parameters were not reported. Secondly, they did not indicate the data to parameter ratio or the 2270 total reflections collected within  $2\theta \le 54^{\circ}$ . Only 1198 independent non-zero reflections were used in the refinement. If the total number of parameters was the same as in the refinement of **6** (total of 255 parameters), the data to parameter ratio would be less than 5:1, an unsatisfactory data set by today's standards and prone to large errors. A new definition of Fe(NO)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> is necessary and is described below.

The refinement of **6** used 3208 independent reflections for 255 parameters, or a ratio of 12.5:1. Figure 2.10 shows the ortep diagram of **6**, Fe(NO)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>. The iron is situated in a *pseudo*-tetrahedral environment with two coordinated NO groups attached through the nitrogen and two triphenyl phosphine groups attached through the phosphorous atom. The nitrosyls are linear, having angles of 177.7(4)°. The O-Fe-O angle is less than the N-Fe-N angle, and fits the definition of an 'attracto' conformation. The angle of N-Fe-N is 124.5(3)°. The angle of P-Fe-P is 111.9(6)°. The nitrosyl groups are better  $\pi$ -acceptors than the PPh<sub>3</sub> ligands and therefore have the larger angle between them. In comparison with **2**, the greater  $\pi$ -accepting ability of the PPh<sub>3</sub> ligand widens the P-Fe-P angle of **6** to 111.9(6)°, whereas the lesser  $\pi$ -acidity of the 1-MeIm group folds in the N<sub>3</sub>-Fe-N<sub>5</sub> angle to 91.2°.

The crystal packing of 6, shown in Figure 2.11, reveals a layering of nitrosyls and a layering of the phenyl groups as observed in the crystal packing of  $[Fe(NO)_2(CO)]_2$ dppe and  $[Fe(NO)_2(CO)]_2$ dppm.<sup>50</sup>

Figure 2.8. Ortep diagram of  $Fe(NO)_2(1-MeIm)_2$  shown at 50 % thermal ellipsoids.

Figure 2.9. Crystal packing diagram of Fe(NO)<sub>2</sub>(1-MeIm)<sub>2</sub>.

Figure 2.10. X-Ray crystal structure of 6, shown with 50 % thermal ellipsoids. Hydrogen atoms have been omitted for clarity.

Figure 2.11. Crystal packing of 6, viewed down the b axis. Hydrogen atom have been omitted for clarity.

## **2.6 Mass Spectrometry**

Analysis of thermally labile organometallic compounds by traditional ionization methods such as electron impact (EI) and chemical ionization (CI) is difficult. Fortunately, the problem has been alleviated to some extent by fast atom bombardment (FAB). For the series of iron dinitrosyl imidazole compounds,  $Fe(NO)_2(L)_2$  [L = imidazole 1, 1-methylimidazole 2, 4-methylimidazole 3, benzimidazole 4, 5,6-dimethylbenzimidazole 5], these conventional ionization techniques provide spectra with no observance of M+, M+ being defined as the sought after molecular ion for the four coordinate compounds of 1 - 5. Recently, techniques have been demonstrated that combine electrospray and electrochemical

Figure 2.12. Schematic diagram of mass spectrometer ionization apparatus.

oxidation (ESCI) that produce intact molecular ions (M+) for a variety of organometallic (and organic) compounds.<sup>51</sup> A drawback of this procedure is the complexity of the methodology used to generate the ions, i.e. interfacing an electrochemical cell with the sample introduction system or the use of mobile phase additives such as dichlorodicyanobenzoquinone (DDQ) to promote the oxidation. Smith has recently developed a modification to the ESCI method without the use of an external electrochemical cell or addition of chemical oxidants.<sup>52</sup> Figure 2.12 shows a schematic diagram of the ESCI apparatus used, in which a potential difference is created between the nebulizing capillary tube (4 - 4.5 kV) and the cone (5 - 15 V). A solution containing the compound approaches the capillary tip where the compound is oxidized during a positive ion mode, under atmospheric pressure. It is believed that the ionization occurs at the tip of the nebulizing capillary when the compounds come in contact with the capillary walls.<sup>53</sup> The ionized compounds pass through the cone and are subjected to a vacuum as they flow towards the quadrupole detector. The mass spectroscopy experiments were carried out using reaction mixtures of the imidazole series of compounds that were worked up in a mixture of 90:10 dichloromethane/methanol, the same solvent composition as the carrier mobile phase. The M+ parent ions observed for compounds 1-5 are listed in Table 2.14. The mass spectra obtained for 1 - 5 are shown in Figures 2.13-2.17, respectively. Figures 2.18a and 2.18b show the simulated and experimental isotopic distribution of the M+ 280 peak for  $Fe(NO)_{2}(1-MeIm)_{2}^{+}$ , respectively. This distribution was used to determine the iron containing compounds in the spectra.

There are two recurring, interesting aspects in each spectra besides the (M+) peaks:

1) a non iron compound that corresponds to twice the MW of the imidazole ligand plus hydrogen [2 Im + H]; and 2) repeating, higher molecular mass peaks beyond M+. The first interesting observation is a dimer of the imidazole ligand linked through a hydrogen atom. Table 2.15 lists the imidazole dimers

Figure 2.14. Mass spectrum of Fe(NO)<sub>2</sub>(1-MeIm)<sub>2</sub>

Figure 2.15. Mass spectrum of Fe(NO)<sub>2</sub>(4-MeIm)<sub>2</sub>

Figure 2.17. Mass spectrum of Fe(NO)<sub>2</sub>(5,6-dimethylbenzimidazole)<sub>2</sub>

Figure 2.18. Isotopic Ratio of Fe(NO)<sub>2</sub>(1-MeIm)<sub>2</sub>

found in each spectrum and Scheme 2.6 shows the proposed structures of each dimer formed. The association of imidazole ligands into long chain oligomers has been previously noted<sup>54</sup> and has been deemed responsible for the high melting points of imidazole, 4-MeIm, Benzim, and 5,6-dimethylbenzim (m.p. 90, 66, 170, and 204°C, respectively) relative to N-protected imidazoles (1-MeIm m.p. -6 °C).

The second unforseen feature of each mass spectrum is the appearance of higher weight molecular peaks than the parent ions. Table 2.16 lists the MW peaks greater than M+ observed for each spectrum, and the corresponding repeating mass difference between higher MW values. Each of the peaks beyond M+ is related to the M+ by the addition of a repeating mass unit, or monomer. In other words, each higher mass peak is an oligomer based on the starting M+ peak in each mass spectrum. The repeat mass unit consists of one iron, two nitrosyls, and one deprotonated imidazole ligand. For the case of Fe(NO)<sub>2</sub>(imidazole)<sub>2</sub>, the M+ peak occurs at m/z 252, with accompanying peaks at m/z 435, 618, and 801. The MW 435 peak would then consist of the M+ parent molecule, plus the iron fragment shown in Scheme 2.7. Correspondingly, the peaks at m/z 618 and 801 are larger oligomers consisting of 3 and 4 iron repeat units attached to M+. The concentration of even higher MW species are of very low intensity, and are lost in the baseline noise.

It is believed that these compounds are a direct result of the environmental conditions set by the mass spectrometer.<sup>55</sup> Point in proof, an experiment was carried out involving a series of injections of a reaction mixture of  $Fe(NO)_2(CO)_2$  with 4-MeIm that was allowed to sit for approximately 10 minutes, 1 hour and one day. All three spectra

obtained were identical. If a polymeric species were formed in solution, a higher molecular weight distribution of ions would be expected after longer periods of time with exposure to the monomer.

Inorganic polymer species with imidazoles and Cu, Co, and Zn have been reported.<sup>56,57,58,59</sup> The iron compound in Figure 2.19,  $[Fe_3(imid)_6(imidH)_2]_x$ ,<sup>60</sup> consists of chains of tetrahedral iron centers cross-linked *via* octahedral iron ions to generate a 3-D array. All of the iron centers are bridged to four other metal centers *via* imidazolate ions, the two remaining (trans) coordination positions of the octahedral centers being occupied by neutral imidazole molecules. The  $[Fe(NO)_2(Im)_2]_x$  oligomer is a linear chain. The nitrosyl ligands replace two coordination sites available on iron and prevent the formation of cross linking between the linear chains of Fe-Im-Fe.

The fact that **2** has a repeat unit of mass 147, as shown in Figure 2.14, is unusual. The tertiary N is protected by a methyl group and is not expected to be available to bridge another iron. Even if the methyl group were removed it would still have a repeat unit of mass 183, 36 mass units higher than that observed. Each of the higher MW peaks is an iron containing compound, as confirmed by their isotopic distribution. MS/MS experiments have only been performed on the M+ 280 peak, so composition of the repeat unit is unknown.

Foffani and co-workers<sup>61</sup> have previously reported the fragmentation pattern for  $Fe(NO)_2(CO)_2$ . The spectrum was obtained with a collision energy of 50 eV. A cascading pattern was observed including ions such as  $Fe(NO)_2(CO)_2^+$  (large),  $Fe(NO)_2(CO)^+$  (2<sup>nd</sup> largest),  $Fe(NO)(CO)_2^+$  (v.small),  $Fe(NO)_2^+$  (small),  $Fe(NO)(CO)^+$  (med),  $Fe(CO)_2^+$ 

(v.small),  $Fe(NO)^+$  (med),  $Fe(CO)^+$  (large),  $FeN^+$  (med),  $Fe^+$  (largest),  $NO^+$  (large),  $CO^+$  (large). The ms/ms experiments were performed on compounds 1 - 5 with more gentle collision conditions than Foffani's work (collision energies no greater than 35 eV, as compared to 50 eV for Foffani). The spectra obtained for compounds 1 - 5 obviously do not have the same degree of fragmentation with the lower collision energy, but the spectra in Figures 2.20 - 2.27 still provide useful information. We observe the characteristic losses of NO and Im ligands for each compound, the fragment ion MW's of which are listed in Table 2.17.

The ESCI technique was used on the  $Fe(NO)_2(1-MeIm)_2$  reaction mixture to try to gain insight into the decomposition of the  $Fe(NO)_2(L)_2$  set of compounds. The dark green mixture was exposed to air and allowed to react, after which, samples of the solution were injected at timed intervals. Figure 2.14 shows the initial spectra before exposure to air. Upon exposure, the solution immediately turned to a clear brown solution. The spectra obtained (Figure 2.28) shows the 280 peak remains the dominant ion peak, with many new peaks appearing lower than 280. Higher MW iron containing peaks are still visible at 427 and 574, but much lower intensity than the 280 peak.

After 5 minutes (Figure 2.29), the solution became cloudy and took on a more orange colour. The M+ 280 was still relatively large, but is no longer the dominant peak. The 165 ion became the largest peak, which corresponds to the 1-MeIm dimer. There are no peaks in the spectrum that are observed as daughters of the 280 peak. An unknown peak appears at 348, almost of the same intensity as the 280 ion. A small peak at 473 is still observed, while the peak at 574 has disappeared. At seven minutes (Figure 2.30), the solution had cleared and a precipitate settled to the bottom of the flask. The ions of mass greater than 400 are no longer discernable above the baseline, and the spectrum is still complex. A large non-iron peak is visible at 105 and becomes the dominant peak. The 280 ion peak is very small and the 165 peak is just slightly smaller than the 105 peak.

After 10 minutes (Figure 2.31), the solution became almost clear, with an orange precipitate covering the bottom of the flask. The solution contains mainly protonated imidazole ligand. A small amount of the dimer 1-MeIm dimer appears at 165. An unknown peak also remains at m/z 105, but much smaller than m/z 165.

These experiments show no characteristic losses of NO and ligand, as found by ms/ms experiments. This infers that the reaction is not proceeding by way of a dissociative ( $S_N1$  type) substitution mechanism and therefore most likely proceeds *via* an associative ( $S_N2$  type) pathway. There are no soluble iron containing compounds in solution after 7 - 10 minutes, which leaves mainly the 1-MeIm ligand (1-MeImH<sup>+</sup>, m/z 83) and the dimer complex (shown in Scheme 2.6 B, m/z 165) as the major species in the spectra. The colour of the precipitate after 7 - 10 minutes is orange, and may be an iron oxide. It is thought that upon exposure of the solution to air, oxygen addition occurs at the iron center to produce a bimolecular intermediate compound. A molecular weight peak reflecting a species of this nature has not yet been deciphered in the spectra.

Compound	M+ (Da/e)
1 $Fe(NO)_2(imidazole)_2$	252.0
2 $Fe(NO)_2(1-MeIm)_2$	280.0
3 $Fe(NO)_2(4-MeIm)_2$	279.9
4 $Fe(NO)_2(Benzimidaole)_2$	352.1
5 $Fe(NO)_2(5,6-dimethylbenzim)_2$	408.2

# 3. Experimental

Tetrahydrofuran (THF) was refluxed over sodium/benzophenone until the mixture became blue/purple. The THF was then distilled and collected under inert nitrogen atmosphere. Diethylether was refluxed over sodium/benzophenone until the mixture became blue. The ether was then distilled and collected under inert nitrogen atmosphere. Dichloromethane and methanol were both refluxed over calcium hydride (CaH<sub>2</sub>) for 24hrs. Dichloromethane and MeOH were then distilled and collected under inert nitrogen atmosphere. Pentacarbonyliron(o), imidazole, 1-methylimidazole, 4-methylimidazole, benzimidazole, 5,6-dimethylbenzimidazole and sodium metal were purchased from Sigma-Aldrich Chemicals and used without further purification. Sodium nitrite was purchased from Fischer Scientific and used without further purification.

Dinitrosyldicarbonyliron(o) and subsequent imidazole complexes were air sensitive. Manipulations were carried out either in a glove bag or in a two station dry box (Innovative Technology), both purged with nitrogen dried by passing through a "Lab Clear" gas drying bottle.

### **<u>3.1 FT-IR Spectroscopy</u>**

IR spectra were recorded on a Bio-Rad FTS-40 spectrometer as KBr pellets or using a  $CaF_2$  solution cell. Solution IR were performed using 2:1 reaction mixtures of the appropriate imidazole ligand and  $Fe(NO)_2(CO)_2$ , in THF. The IR spectrum for  $Fe(NO)_2(CO)_2$  was obtained by dissolving it in ether and using a NaCl solution cell.

#### 3.2 Nuclear Magnetic Resonance (NMR)

All NMR spectra were recorded on either a Bruker AC-200 (<sup>1</sup>H 200MHz, <sup>13</sup>C 50MHz) or AC-300 (<sup>1</sup>H 300MHz, <sup>13</sup>C 75MHz) spectrometer. Samples were prepared under nitrogen in a glove-bag by performing the reactions in deuterated methanol, in a reaction flask fitted with a young valve and a side arm with an NMR tube attached by a 1/4" Swagelok ultra-torr connector. After CO evolution subsided, the mixture was poured through the side-arm, into the NMR tube, frozen and flame sealed.

 $Fe(NO)_2(CO)_2$  was filtered through glass wool and washed with one ampule of deuterated MeOH. Following this was the imidazole ligand, dissolved in one ampule of d-MeOH.

#### **<u>3.3 Electron Paramagnetic Resonance Spectroscopy (EPR)</u>**

All EPR spectra were recorded on a Bruker EMX 8/2.7 spectrometer, operating at a frequency of 9.4 GHz (X–band) with a magnetic field modulation of 100 kHz and equipped with a variable-temperature device. Samples were prepared under nitrogen in a glove bag. A solution of  $Fe(NO)_2(CO)_2$  dissolved in THF was added through a glass wool filter to a reaction flask fitted with a young valve and a side arm with a quartz micro-EPR tube. A 2 molar equivalent of the appropriate imidazole ligand , dissolved in THF, was then added through a glass wool filter to the reaction flask. Spectra were obtained immediately.

### 3.4 X-ray crystallography

X-ray crystallographic data for 2 were collected from a single crystal sample, which had been place on a glass fibre, mounted 6mm above a brass pin, using paraffin oil as the adhesive. The X-ray crystallographic data for 6 were collected from a single crystal sample, which had been mounted on a glass fibre, 6mm above a brass pin, using epoxide glue as the adhesive. Both data sets were collected at -60°C, using a P4 Siemens diffractometer, equipped with a Siemens SMART 1K Charged-Coupled Device (CCD) Area Detector (using the program SMART) and a rotating anode using graphitemonochromated Mo-Kalpha radiation (lambda = 0.71073 A). The crystal-todiffractometer distance was 3.9991 cm and the data collection was carried out in 512 X512 pixel mode, utilizing  $2 \ge 2$  pixel binning. The initial unit cell parameters were determined by least-squares fit of the angular settings of the strong reflections, collected by a 4.4 degree scan in 15 frames over three different parts of reciprocal space (45 frames total). After one complete hemisphere of data collection, the first frames were recollected in order to improve the decay corrections analysis. Processing was carried out by the use of the program SAINT, which applied Lorentz and polarization corrections to threedimensionally integrated diffraction spots. The program SADABS was utilized for the scaling of diffraction data, the application of decay correction, and an empirical absorption correction based on redundant reflections.

The structures of 2 and 6 were solved by using the direct methods procedure in the Siemens SHELXTL program library, and refined by full-matrix least squares methods with anisotropic parameters for all atoms, except the methyl hydrogens at the C4 and C8 positions of **2**. The hydrogens of the C4 and C8 atoms of **2** were generated at calculated positions, with thermal parameters based on the carbons to which they are attached.

### 3.5Mass Spectra

Pneumatically assisted electrospray (ES) was performed with either DCM or a mixture of 90/10 dichloromethane/methanol as the mobile phase at a flow rate of 10µL/min employing a Brownlee Microgradient syringe pump. Samples were prepared by reacting  $10\mu l$  ( 8.727 x  $10^{-5}$  mol) Fe(NO)<sub>2</sub>(CO)<sub>2</sub> with 1.7454 x  $10^{-4}$  mol of imidazole ligand in either 10mL DCM or MeOH and were introduced by loop injection (10µL). Data was acquired in MCA mode. Full scan positive ion ES experiments (MS and MS/MS) were performed with a Micromass Quattro-LC triple quadrupole instrument. The PEEK tubing and fittings were replaced with either stainless steel or teflon. A Rheodyne 7125 HPLC injection valve was connected to the ES probe with ~10cm of teflon tubing to allow sample introduction to take place as close as possible to the exit of the stainless steel ES capillary. Operating parameters were as follows: source temperature 80°C, cone voltage (CV) 5 - 15V (normally 35V or greater) and a capillary voltage of 4 - 4.5 kV (normally 3 - 3.5kV). Argon was used as the collision gas for MS/MS experiments at a gas cell pressure of ~  $2 \times 10^{-3}$  mBar.

### **<u>3.6 Synthesis of Complexes</u>**

#### Synthesis of Dinitrosyldicarbonyliron(0)

Dinitrosyldicarbonyliron(0) was synthesized by a modified method of Seel.<sup>62</sup> Twenty five milliliters of Ironpentacarbonyl (0.20 mol) was dissolved in 400mL of methanol, along with 10g (0.44 mol) sodium metal and 17g (0.25 mol) sodium nitrite. The solution was refluxed until the distillate no longer showed a yellow colour. The methanol was distilled off at 70°C to leave a dry yellow product, Na[Fe(NO)(CO)<sub>3</sub>]. 400mL of distilled H<sub>2</sub>O was added and 17g (0.25 mol) of sodium nitrite. The solution was purged with a slow flow of CO<sub>2</sub> and the yellow/orange gas evolved was collected in a series of 3 U-tubes as a brick red solid, at -78°C in a dry ice/acetone bath. The yield was 20g (60%). MW = 171.88g/mol; d = 1.56 g/cm<sup>3</sup>; m.p. = 21.6 °C; IR (in ether): v(NO): 1810 cm<sup>-1</sup>, 1767 cm<sup>-1</sup>; v(CO) : 2087 cm<sup>-1</sup>, 2038 cm<sup>-1</sup>.

### Synthesis of Diimidazoledinitrosyliron(0) (1)

Fe(NO)<sub>2</sub>(CO)<sub>2</sub> (0.1mL, 8.727 x 10<sup>-3</sup> mol) was added to a solution of 0.10g ( 0.01745 mol) of imidazole dissolved in 1mL of ether. Gas evolved, and within two minutes the solution turned from a red to a green colour. The solvent was removed by reduced pressure. The solid was washed three times with ether and decanted each time. After the final wash, the solid was dried under reduced pressure at room temperature. Yield 68 %; MW 250g/mol ; M+ 250 m/z, 222 (M+ -NO), 191 (M+ - 2NO), 184 (M+ -Im), 154 (M+ -NO, Im); IR: $v_{(NO)}$  1680, 1622 cm<sup>-1</sup>; EPR: g 2.0344, a<sub>n1</sub> 3.3, a<sub>n2</sub> 2.4, 2 X a<sub>n3</sub> 2.1 G.

# Synthesis of Di(1-methylimidazole)dinitrosyliron(0) (2)

 $Fe(NO)_2(CO)_2$  (0.1mL, 8.727 x 10<sup>-3</sup> mol) was added to a solution of 0.120mL ( 0.01745 mol) of 1-methylimidazole dissolved in 1mL of ether. Gas evolved, and within two minutes the solution turned from a red to a green colour. The solvent was removed by reduced pressure. The solid was washed three times with ether and decanted each time. After the final wash, the solid was dried at reduced pressure and at room temperature. Yield 87 %; MW 280 g/mol ; M+ 280 m/z, 250 (M+ - NO), 220 (M+ -2NO), 168 (M+ - NO, 1-MeIm) ; IR v<sub>(NO)</sub> 1673, 1616 cm<sup>-1</sup>; EPR g 2.0275, 2 X a<sub>n1</sub> 2.9, 2 X a<sub>n2</sub> 2.6 G.

### Synthesis of Di(4-methylimidazole)dinitrosyliron(0) (3)

 $Fe(NO)_2(CO)_2$  (0.1mL, 8.727 x 10<sup>-3</sup> mol) was added to a solution of 0.120g ( 0.01745 mol) of 4-methylimidazole dissolved in 1ml of ether. Gas evolved, and within two minutes the solution turned from a red to a green colour. The solvent was removed by reduced pressure. The solid was washed three times with ether and decanted each time. After the final wash, the solid was dried under reduced pressure at room temperature. Yield 62 %; MW 280 g/mol; M+ 280 m/z, 250 (M+ - NO), 220 (M+ -2NO), 168 (M+ - NO, 1-MeIm), M+ 477 m/z, 477 (M+), 447 (M+ - NO), 417 (M+ -2NO), 395 (M+ - 4-MeIm), 365 (M+ - NO, 4-MeIm), 335 (M+ - 2NO, 4-MeIm); IR v<sub>(NO)</sub> 1677, 1620 cm<sup>-1</sup>; EPR g 2.0336, a<sub>n1</sub> 3.1, a<sub>n2</sub> 2.5, 2 X a<sub>n3</sub> 2.2 G.

# Synthesis of Di(benzimidazole)dinitrosyliron(0) (4)

Fe(NO)<sub>2</sub>(CO)<sub>2</sub> (0.1mL, 8.727 x 10<sup>-3</sup> mol) was added to a solution of 0.173g ( 0.01745 mol) of benzimidazole dissolved in 1mL of THF. Gas evolved, and within two minutes the solution turned from a red to a green colour. The solvent was removed by reduced pressure. The solid was washed three times with ether and decanted each time. After the final wash, the solid was dried under reduced pressure at room temperature. Yield 68%; MW 352 g/mol ; M+ 352 m/z, 322 (M+ - NO), 292 (M+ - 2NO), 234 (M+ - benzim), 204 (M+ - NO, benzim), 585 m/z (M+), 555 (M+ - NO), 525 (M+ - 2NO), 477 (M+ - benzim), 437 (M+ - NO, benzim); IR  $\nu_{(NO)}$  1682, 1625 cm<sup>-1</sup>; EPR g 2.0341,  $a_{n1}$  3.8,  $a_{n2}$  2.4, 2 X  $a_{n3}$  1.9.

#### Synthesis of Di(5,6-dimethylbenzimidazole)dinitrosyliron(0) (5)

Fe(NO)<sub>2</sub>(CO)<sub>2</sub> (0.1mL, 8.727 x 10<sup>-3</sup> mol) was added to a solution of 0.213g ( 0.01745 mol) of 5,6-dimethylbenzimidazole dissolved in 1mL of THF. Gas evolved, and within two minutes the solution turned from a red to a green colour. The solvent was removed by reduced pressure. The solid was washed three times with ether and decanted each time. After the final wash, the solid was dried under reduced pressure at room temperature. Yield: 81 %; MW: 408 g/mol; M+ 408 m/z, 378 (M+ - NO), 348 (M+ - 2NO), 262 \*, 232 (M+ - 5,6dimethylbenz), 202 (M+ - NO, -5,6dimethylbenz); IR: $v_{(NO)}$  1683, 1625 cm<sup>-1</sup>; EPR g 2.0344,  $a_{n1}$  3.9, 2 X  $a_{n2}$  2.2.

# Synthesis of dinitrosylcarbonyltriphenylphospineiron(0)

 $Fe(NO)_2(CO)_2$  (0.45mL, 4.11 x 10<sup>-3</sup> mol) was added *via* a syringe to a stirred solution of triphenylphosphine (1.11g, 4.23 x 10<sup>-3</sup> mol) in diethylether (10 mL), in an Erlenmyer flask fitted with a rubber septum . The flask received a positive pressure of nitrogen via a syringe. The dark red solution was stirred overnight at room temperature. The solvent was removed under reduced pressure and the dried red solid was washed with methanol.

# Synthesis of Dinitrosyl-bis(triphenylphosphine)iron(0). (6)

 $0.02 \text{ ml} (1.23 \text{ x } 10^{-4} \text{ mol}) \text{ of } 1$ -methylimidazole was added to a solution of 0.01 g(1.23 x  $10^{-4} \text{ mol}) \text{ Fe}(\text{NO})_2(\text{CO})(\text{PPh}_3)$  dissolved in 5 ml of diethylether in a glass test tube. The red solution was stoppered and turned dark red/green after one day, during which, large cubic crystals formed. A dark red crystal was obtained which provided the X-ray crystal structure of **6**. Yield, IR and EPR were not performed.

#### **FUTURE WORK and CONCLUSIONS**

First, and foremost, research into the methods of purification of these compounds should be undertaken. State of the art vacuum line techniques, similar to that presented by Burford,<sup>63</sup> would provide an excellent vehicle for advancement of this field. Electrochemical studies should be performed to further support the mechanistic pathway presented. Formation of an Im<sup>-</sup> species would provide almost conclusive results that the process does occur by a catalytic 17-electron electron transfer chain mechanism (ETC). Also, the nature of the colour change from green to brown may be by an electronic means and electrochemistry may help support this idea. It is believed that either a one electron oxidation to the 17 electron complex, or one electron reduction to the 18 electron complex is the driving force for the colour change by some species in solution. Constant voltage experiments on bulk solutions may provide the means for a colour change of the solution. MS/MS experiments must be performed on the m/z peaks of 2. The repeat unit of 147 mass units observed for these peaks is an iron containing compound, but is 36 mass units less than the repeat unit observed for 1, which should be the smallest repeat unit for the series.

The syntheses of the  $Fe(NO)_2(L)_2$  [ L = imidazole 1, 1-methylimidazole (1-MeIm) 2, 4-methylimidazole (4-MeIm) 3, benzimidazole (benzim) 4, and 5,6dimethylbenzimidazole (56benzim) 5 ] series of compounds open the door to further research of biologically relevant iron nitrosyl chemistry. One future goal, is to mimic NO transport. Elegant studies performed by Doyle<sup>64,65</sup> and Kadish<sup>66,67</sup> have shown that the NO ligand may be removed from an iron or cobalt center of porphyrin complexes by oxidizing the metal center. The higher the oxidation state, the weaker the metal nitrosyl bond and the more readily NO is released. It may be a process similar to this that allows metal mediated transfer in the human body. The  $d^{10}$  iron nitrosyl compounds have very strong M-N bonds and will not easily relinquish NO. Oxidation of compounds 1 - 5 would only provoke further instability and so it is not likely that these complexes would be a good illustration of species that release NO. Complexes 1 - 5 may then be more representative of an iron molecule *after* receiving NO. The goal then is to create a molecule which would accept NO to create the final products 1 - 5. The use of a series of iron carbonyl imidazole complexes of the form  $Fe(CO)_3(L)_2$  seem a likely choice as receptors of NO gas bubbled through solution. Substitution of three CO ligands by two NO ligands would create the 18 electron complexes of 1 - 5.

The chemical sensitivity of the  $Fe(NO)_2(L)_2$  series of compounds has precluded purification and isolation of theses products. However, studies of reaction mixtures have elucidated the 17-electron ETC mechanistic pathway by which they are formed. Supporting evidence of the pathway is provided by IR, EPR and Mass spectroscopic studies. X-ray crystallography of 2 has shown that the four coordinate complexes are of a *pseudo*-tetrahedral geometry.
