TITLE: Two-Pion Exchange Three-Body Force in Nuclear Matter  

AUTHOR: Carl K. Ross, B.Sc.  

SUPERVISOR: Dr. R. K. Bhaduri  

NUMBER OF PAGES: v, 71  

SCOPE AND CONTENTS:

The two-pion exchange three-body nuclear force is discussed, and an effective two-body interaction derived which is capable of reproducing approximately its effect in nuclear matter. Treating the three-body interaction as a perturbation, the first order contribution to the binding energy of nuclear matter is derived using the actual three-body interaction, the effective interaction, and a recently suggested method in which the three-body effects are taken approximately into account by modifying the pion mass in the one-pion exchange potential. Although the latter method leads to a simple prescription for calculating the three-body effects when no nucleon-nucleon cut-off is applied, the calculation is shown to be considerably more difficult for the realistic case when a cut-off is introduced, and the modified pion mass is momentum dependent.

On the other hand, the effective interaction is found to reproduce quite well the actual three-body effects.
in first order. This fact is used as a basis for calculating the second order contribution using the effective interaction, and so an estimate of the three-body effects in nuclear matter is obtained. For a reasonable value of nucleon-nucleon cut-off, the three-body forces are shown to contribute approximately 6 MeV additional binding to nuclear matter.
ACKNOWLEDGEMENTS

The main body of this thesis grew out of work begun during the past year by Dr. R. K. Bhaduri and Professor Y. Nogami in connection with a paper on the three-body nuclear force which had recently appeared in the literature. I am very appreciative of their continued interest and personal involvement in the project which has helped to lead to its rapid conclusion.

I would like to extend special thanks to my supervisor, Dr. Bhaduri, whose assistance and advice over the past year has been instrumental in maintaining my interest in the project. Also important, particularly during the latter stages of the work, were several discussions with Professor Nogami which helped to clarify many difficult points.

I would also like to thank all the faculty and graduate students in the Theoretical Physics Group at McMaster for providing a stimulating atmosphere in which to work, and one of the secretaries, Mrs. Ursula Blake, for carefully typing the manuscript.

The financial assistance, in the form of a postgraduate scholarship, of the National Research Council of Canada is gratefully acknowledged.

CHAPTER 1

INTRODUCTION

The study of the two nucleon interaction has been a fundamental problem in nuclear physics, and although the processes involved are not yet completely understood, enough experimental data has been accumulated so that accurate phenomenological\(^1\) or semi-theoretical\(^2\) potentials can be constructed. These two-body potentials have then been applied in calculations involving many-body systems, on the assumption that many-body interactions are negligible. However, from a meson-theoretical point of view, many-body forces may well be important, and in particular the three-body force may play a significant role in determining the binding energy of a many-nucleon system.

The possibility of three-body forces in many-nucleon systems has been discussed for some time\(^3\), and the effects due to both two-pion and three-pion exchange processes in some many-body systems have been considered. Bhaduri, Loiseau and Nogami\(^5\) (to be referred to as BLN) have pointed out that for the case of hypernuclei the three-body two-pion exchange process may be expected to play an important role and have calculated the effects of such a force to first order in nuclear matter. More recently, Brown and Green\(^7\) (to be
referred to as BG) have examined the NNN interaction in nuclear matter, and have shown that, under certain assumptions, the three-body interaction due to the two-pion exchange (TPE) process may be considered as an effective two-body interaction, similar in form to the one-pion-exchange potential (OPEP), but with a modified pion mass. By using this method, BG do not need to find the effective interaction in coordinate space, and so the perturbation calculation is simple, at least for the case in which no nucleon-nucleon cut-off is introduced. As will be shown later, the prescription is not as simple when an NN cut-off is applied and the modified pion mass is momentum dependent.

In this work, the effective interaction due to the three-body force will be derived in coordinate space, and the contribution of this interaction to the binding energy of nuclear matter will be calculated to second order. Considerable attention will be devoted to the first order calculation, where it will be shown how this interaction is related to the more conventional three-body interaction of BLN, and to the effective mass approach of BG. Although the primary process to be considered is the TPE, some higher order effects will be taken into account through the introduction of pionic form factors \((8,9)\). It will be seen that these form factors tend to suppress the high momentum components of the potential, so that even though the effective interaction derived here and the potential of BLN differ in some singular contact terms
characteristic of high momentum components, for realistic form factors the two give very similar results when calculated to first order.

As will be shown in Chapter II, the perturbation series will require a knowledge of the two-body as well as the three-body force in order to obtain the total second order contribution. In principle, one of the two-body interactions mentioned earlier which fit all the available two-nucleon scattering data could be used. Instead, the tail of the OPEP will be used, in the spirit of the Møzkowski-Scott separation method\(^\text{(10)}\). Two reasons motivate this choice. Firstly, it is well known that for large distances \((r>2F)\) the OPEP approximates quite well the actual nucleon-nucleon interaction. Secondly, by using the OPEP with a cut-off at small distances, analytic evaluation of most of the required results will be possible, a situation which would not normally prevail with a more complicated NN interaction. For comparison purposes, the OPEP contribution to nuclear matter will also be calculated. This will permit an accurate estimation of the relative importance of the three-body interaction, both in first and second order.

In Chapter II the Rayleigh-Schrodinger perturbation series to second order will be discussed briefly, and the single exchange terms separated out for special consideration. In Chapter III the three-body interaction for the TPE process
will be discussed, and from it the effective two-body interaction, which is to be used in the remaining calculations, will be derived. The first order effects of the BLN potential, the BG potential, and the effective interaction expressed in coordinate space will be discussed in detail, and differences and similarities pointed out. The second order calculation for the effective interaction will be derived in Chapter V, and numerical results given in Chapter VI. Finally, the importance of the three-body interaction will be discussed, and some of the remaining difficulties and ambiguities mentioned.
CHAPTER II

PERTURBATION SERIES TO SECOND ORDER

Nuclear matter, although a theoretical construct, has been a useful many-body system for testing the effects of an assumed nuclear force. It consists of an infinite array of equal numbers of protons and neutrons, uniformly distributed in space, but with the Coulomb interaction between the protons inoperative. This means that the only interaction between the nucleons is due to the nuclear force, and because the system is infinite in extent, surface effects do not complicate the analysis. The main interest here will not be in constructing a combined two and three-body interaction which can reproduce the expected binding energy per particle at the equilibrium density, but rather in determining the relative importance of the three-body as compared to the two-body force.

The approximate effect of the TPE three-body force to nuclear matter will be estimated using the Rayleigh-Schrodinger perturbation series to second order. The system Hamiltonian will be written as

\[ H_t = H_0 + H', \]  

(1)

where \( H_0 \) is the unperturbed Hamiltonian, consisting of any
effective one-body potential generated by the system of nucleons, and $H$ is the perturbation which in this case will consist of the sum of a two and three-body interaction. Because of the translational invariance of nuclear matter, any effective one-body interaction must be independent of the position variable, and so the unperturbed system wave functions, $|\phi_n>(n=0,1,2\ldots)$, must be Slater determinants of plane waves. These single particle wave functions will be assumed to satisfy periodic boundary conditions in a large but finite volume $\Omega$, which will eventually be allowed to approach infinity.

The interaction term $H$ may be written as

$$H = V + W$$

where $V$ and $W$ are given by

$$V = \frac{1}{2} \sum_{i,j} v(r_i, r_j) \quad \text{and} \quad W = \frac{1}{2} \sum_{i,j,k} w(r_i, r_j, r_k) ,$$

with $v$ and $w$ being respectively the OPEP, and the three-body potential to be derived in the following chapter. The variable $r_i$ is the position vector of the particle in the $i$th state, and the sums are over all occupied single particle states. To second order, the energy shift $\Delta E$ due to the perturbation $H$ is given by

$$\Delta E = \langle \phi_0 | V+W | \phi_0 \rangle + \langle \phi_0 | (V+W) 1/[(V+W)] | \phi_0 \rangle .$$
where
\[
\frac{1}{b} = \frac{1 - |\phi_0\rangle\langle\phi_0|}{E_0 - H_0},
\]

with \(E_0\) being the unperturbed ground state energy. The terms containing only the two-body interaction are

\[
\Delta E^{(1)}(OPEP) = \langle\phi_0|V|\phi_0\rangle,
\]

and

\[
\Delta E^{(2)}(OPEP) = \langle\phi_0|V\ 1/b\ V|\phi_0\rangle.
\]

The standard reduction of these expressions in terms of plane wave states gives

\[
\Delta E^{(1)}(OPEP) = \frac{1}{2} \sum_{i,j} \langle ij|V|ij-ji\rangle,
\]

and

\[
\Delta E^{(2)}(OPEP) = \frac{1}{2} \sum_{i,j} \sum_{i',j'} \frac{\langle ij|V|i'j'\rangle\langle i'j'|V|ij-ji\rangle}{\varepsilon_i + \varepsilon_j - \varepsilon_{i'} - \varepsilon_j'},
\]

where \(\varepsilon_v\) is the energy of the particle in the state \(v\). The state labels \(i\) and \(j\) contain all the quantum numbers necessary to specify the single particle states, and the sums over \(i\) and \(j\) are to be taken over all occupied levels, while the corresponding sums over \(i'\) and \(j'\) are over all unoccupied levels. The diagramatic representation of these two-body contributions is given in figure 1, where the wavy line denotes the interaction \(v\). (For simplicity, all the terms of the perturbation series will be represented by open-ended, rather than closed-loop, diagrams).
Figure 1. Schematic of the first and second order two-body contributions to nuclear matter. a) and b) are the first order, c) and d) the second order direct and exchange contributions. The wavy line denotes the two-body interaction.

Figure 2. Schematic of the three-body cross term contributions, $<V_{1/b}\ W>$, to nuclear matter. a) and b) represents the direct and single exchange contributions, while c) is one of two double exchange contributions.
Consider next the cross term involving both \( V \) and \( W \),
given by
\[
\Delta E^{(2)}(\text{C.T.}) = \langle \phi_0 | V \frac{1}{2b} W | \phi_0 \rangle ,
\]
where the abbreviation C.T. stands for "cross term". Because of the presence of the two-body operator, any intermediate states can differ in at most two single particle excitations from the ground state. Since single particle excitations are not permitted because of the requirement of the conservation of linear momentum, only two particle excitations are possible, and these give rise to several diagrams, some of which are shown in figure 2. The assumption will now be made that the major contribution of the three-body force comes from the single exchange terms, so that diagrams such as figure 2c may be neglected. The validity of this assumption will be discussed later, but accepting it for the time being permits \( \Delta E^{(2)}(\text{C.T.}) \) to be written as
\[
\Delta E^{(2)}(\text{C.T.}) = \frac{1}{2} \sum_{i,j,k} \sum_{i',j'} \langle ijk | V | i'j'k \rangle \langle i'j'k | W | ijk-jik \rangle \frac{\epsilon_i + \epsilon_j - \epsilon_i - \epsilon_j}{\epsilon_i^2 - \epsilon_j^2} .
\]

Because of the Hermitian nature of \( V \) and \( W \),
\[
\langle \phi_0 | V \frac{1}{2b} W | \phi_0 \rangle = \langle \phi_0 | W \frac{1}{2b} V | \phi_0 \rangle ,
\]
and so the total contribution to the second order energy due to the cross terms is \( 2 \Delta E^{(2)}(\text{C.T.}) \).

Finally, there are the terms involving only three-
body interactions, given by

$$\Delta E^{(1)}(\text{T.B.}) = \langle \phi_0 | W | \phi_0 \rangle , \quad (12)$$

$$\Delta E^{(2)}(\text{T.B.}) = \langle \phi_0 | W \ 1/b \ W | \phi_0 \rangle , \quad (13)$$

where the abbreviation T.B. stands for "three body". Again assuming that the major contribution to $\Delta E^{(1)}(\text{T.B.})$ and $\Delta E^{(2)}(\text{T.B.})$ is given by single exchange terms, these expressions simplify to

$$\Delta E^{(1)}(\text{T.B.}) = \frac{1}{2} \sum_{i,j,k} \langle ijk | w | ijk - jik \rangle , \quad (14)$$

and

$$\Delta E^{(2)}(\text{T.B.}) = \frac{1}{2} \sum_{i,j,k} \sum_{i',j',l} \frac{\langle ijk | w | i'j'k \rangle < i'j'l | w | ijk - jil \rangle}{\epsilon_i + \epsilon_j - \epsilon_{i'} - \epsilon_{j'}} \quad (15)$$

The diagramatic representation of these contributions is given in figures 3 and 4.

As can be seen from figures 2 through 4, if only single exchange terms are considered, the nucleon in the $k^{\text{th}}$ (or $\ell^{\text{th}}$) state is always a spectator. This fact permits the derivation of an effective interaction, for on inspecting equations (10), (14), and (15), it will be seen that a term of the form $\langle k | w | k \rangle$ (or $\langle \ell | w | \ell \rangle$) can be immediately evaluated, and the sum over $k$ (or $\ell$) performed to give $N$, the number of nucleons present. This integration over $\mathbf{r}_k$ gives $u(r_{i'j'})$, the effective interaction due to the three-body force. Then

$$U = \frac{1}{2} \sum_{i,j} u(r_{i'j'}) ,$$
Figure 3. Schematic of the first order contribution of the three-body force to nuclear matter. a) is the direct contribution, b) the single exchange contribution.

Figure 4. Schematic of the second order three-body contribution, \( <U 1/b U> \), to nuclear matter. a) is the direct contribution, b) the single exchange contribution.
with

$$u(r_i, r_j) = \frac{N}{\Omega} \int dr_k \, w(r_i, r_j; r_k) ,$$

(16)

and equations (10), (14), and (15) become

$$\Delta E^{(2)} (\text{C.T.}) = \frac{1}{2} \sum_{i,j} \sum_{i',j'} \langle ij | v | i'j' \rangle \langle i'j' | u | ij-ji \rangle \epsilon_{i+j} \epsilon_{i'-j'} - \epsilon_{i'-j} - \epsilon_{i+j} ,$$

(17)

$$\Delta E^{(1)} (\text{T.B.}) = \frac{1}{2} \sum_{i,j} \langle ij | u | ij-ji \rangle ,$$

(18)

and

$$\Delta E^{(2)} (\text{T.B.}) = \frac{1}{2} \sum_{i,j} \sum_{i',j'} \langle ij | u | i'j' \rangle \langle i'j' | u | ij-ji \rangle \epsilon_{i+j} \epsilon_{i'-j'} - \epsilon_{i'-j} - \epsilon_{i+j} .$$

(19)

In the following chapter the form of $u$, based on the definition given in equation (16) will be found, and in Chapters IV and V explicit expressions for the first and second order contributions of $v$ and $u$ will be derived. It is worth noting that similar expressions hold for a $\Lambda$-particle embedded in nuclear matter, the only difference being in the form of $u$. In this case, the perturbation expansion to second order given above is exact, with the $k$th nucleon state being replaced by that of the $\Lambda$-particle, for the $\Lambda$-particle is of necessity a spectator, and so only single exchange terms can contribute.
Quantum field theory attributes the nuclear force to the exchange of virtual mesons between the interacting nucleons. Besides being an intuitively satisfactory description of the interaction mechanism, this method of analysis permits the nuclear force to be described in terms of a series of processes, the importance of which depends mainly on the nucleon separation. Hence at large distances, the one-pion exchange process is believed to be the main contributor to the two-nucleon force, while at smaller distances, higher order processes, such as the exchange of more than one meson, or the exchange of heavier mesons, become important. In a similar way, the three-body force can be described in terms of meson exchange, and the lowest order process which contributes is the two-pion exchange depicted in figure 5a.

Although the TPE is the fundamental process to be considered, it is nevertheless possible to include in an approximate way higher order effects, such as those depicted in figure 5b, through the use of pionic form factors. Their effect is similar to that obtained by introducing an NN cut-off when considering the two-nucleon interaction, in that they suppress the effects of the short range part of the
Figure 5. The process which gives rise to the TPE three-body force is shown in a), where the blob on the N\textsubscript{3} line represents the N\textsuperscript{*} resonance. In c) the geometry of the situation is sketched, while b) is a schematic of some higher order processes which are included in the form factors.
potential, although the suppression is less severe than with a cut-off. The functional dependence of the form factors has considerable theoretical and experimental basis (8, 9), and the following form will be assumed:

\[ \frac{K^2(q^2) K'(q^2)}{q^2 + \mu^2} = \int_0^\infty \frac{\alpha(m^2) dm^2}{q^2 + m^2}, \]  

where \( K \) and \( K' \) are the vertex and propagator form factors respectively, \( \mu \) is the pion mass, and the spectral function, \( \alpha(m^2) \), will be assumed to have the form

\[ \alpha(m^2) = \delta(m^2 - \mu^2) - (1-\xi) \delta(m^2 - \eta^2), \]  

where \( \xi \) and \( \eta \) are constants which can be partially fixed by experiment. Different values of \( \xi \) and \( \eta \) give rise to different form factors, and calculations will be performed with two sets of reasonable values.

The three-body interaction due to figure 5a will be derived in the static approximation in which the assumption is made that the three nucleons are at rest, and that the energy of the exchanged pions approaches zero. For the single exchange terms, the nucleon labelled \( N_3 \) in figure 5a always appears as a spectator particle, and so the S-matrix for this process is identical to that for the \( \Lambda NN \) case given in reference 5, where \( N_3 \) takes the place of the \( \Lambda \) particle. Then in units of \( \hbar = c = 1 \),

\[ S = \frac{4\pi f^2_N}{(2\pi)^6 \mu^2} \int dq_1 dq_2 \frac{(q_1 \cdot q_1)(q_2 \cdot q_2) \langle q_1 | S^{(3)}_{\pi N} | q_2 \rangle}{(q_1^2 + \mu^2)(q_2^2 + \mu^2)} \]
where $f_N^2$ is the pseudovector $\pi N$ coupling constant, $q_1$ and $q_2$ are the momenta of the exchanged pions, and $\vec{r}_1$ and $\vec{r}_2$ are the coordinates of the nucleons $N_1$ and $N_2$. $g_1$ and $g_2$ are the Pauli spin matrices for the two nucleons, while $\vec{r}_1$ and $\vec{r}_2$ are the corresponding isospin matrices. The scattering matrix, $<q_1|S_{\pi N}^{(3)}|q_2>$, for a zero-energy pion is given by

$$<q_1|S_{\pi N}^{(3)}|q_2> = 2\pi i \delta(0) K(q_1) K(q_2) \{ (\sigma_3 \cdot q_1)(\sigma_3 \cdot q_2) + (\omega_3 \cdot q_1)(\omega_3 \cdot q_2) \} + 2D \} e^{i(q_1-q_2) \cdot r_3},$$

where $A$, $B$, and $D$ are constants in the nonrelativistic approximation, with $(A+B)$ being related to the p-wave $\pi N$ scattering, while $D$ is related to the s-wave scattering.

Since experimentally the $\pi N$ s-wave scattering is known to be very small, $D$ will be taken to be zero. When equation (23) is substituted in equation (22), the $S$ matrix takes the form

$$S = -2\pi i \delta(0) w,$$

where

$$w = \frac{4\pi F_N^2}{2\mu^2} (A+B) \int dq_1 dq_2 \frac{K(q_1) K(q_2)}{q_1^2 + \mu^2} \frac{K'(q_1') K'(q_2')}{q_2'^2 + \mu^2}$$

$$X[(\sigma_3 \cdot q_2)(\sigma_3 \cdot q_1) + (\omega_3 \cdot q_1)(\omega_3 \cdot q_2)] e^{-i(q_1 - q_2) \cdot r_3}.$$
and is interpreted as the three-body interaction. From this expression it will be shown how the potential of BLN, the modified pion mass approach of BG, and the effective interaction in coordinate space may be derived.

In order to derive the three-body potential of BLN, consider initially the case in which

$$H(q^2) \equiv k^2(q^2) \kappa'(q^2) = 1.$$  \hfill (26)

Because the integrals over $q_1$ and $q_2$ in equation (25) are divergent, it is necessary to remove the singular terms appearing in $w(r_1, r_2; r_3)$ due to these divergences, and the standard procedure is to replace

$$\sigma \cdot q \text{ by } -\sigma \cdot \nabla r.$$  \hfill (27)

where the coordinate variable $r$ corresponds to the momentum variable $q$, and remove it from the integral. The integrations over $q_1$ and $q_2$ may now be done using equation A2, and after applying the gradient operators using equation A7, the following expression for $w$ is obtained:

$$w(x, y) = \frac{C_0}{g} \tau_1 \cdot \tau_2 \left\{[\sigma_2 \cdot \sigma_3 + S_{23}^\wedge(y) T_\mu(y)] Y_\mu(y), \right.$$  \hfill (28)

$$\left.\left\{[\sigma_1 \cdot \sigma_3 + S_{13}^\wedge(x) T_\mu(x)] Y_\mu(x)\right\}_+\right.$$  \hfill (28)

where $x = r_1 - r_3$, $y = r_2 - r_3$, and $\{A, B\}_+ = AB + BA$. The functions appearing in equation (28) are defined as follows:

$$S_{lm}^\wedge(\hat{r}) = 3(\sigma_\wedge \cdot \hat{r})(\sigma_\wedge \cdot \hat{r}) - \sigma_\wedge \cdot \sigma_\wedge,$$
\[ T_\mu (r) = 1 + \frac{3}{\mu r} + \frac{3}{(\mu r)^2}, \]

\[ Y_\mu (r) = e^{-\mu r}/\mu r, \]

with \( c_p \) given by (12)

\[ c_p = \frac{\mu f_N^2 (A+B)}{4\pi} = \frac{\mu f_N^2}{9\pi^2} \int_0^\infty \frac{\sigma_{33}(p)dp}{p^2 + \mu^2}, \]

where \( \sigma_{33}(p) \) is the cross section in the \( \pi+N\rightarrow N^* \) reaction.

The anticommutator in equation (28) may be expanded to give more explicitly

\[ w(x,y) = -\frac{c_p}{9} (\tau_1 \cdot \tau_2) \{ 2\sigma_1 \cdot \sigma_2 + 2S_{12}(\hat{y}) T_\mu (y) + 2S_{12}(\hat{x}) T_\mu (x) \]

\[ + [18(\sigma_{11} \cdot \hat{y})(\sigma_{22} \cdot \hat{x})(\hat{x} \cdot \hat{y}) - 2S_{12}(\hat{x}) - 2S_{12}(\hat{y}) \]

\[ - 2\sigma_{11} \cdot \sigma_2 T_\mu (x) T_\mu (y)] \} Y_\mu (x) Y_\mu (y). \]

Consider now the case when form factors are included.

The only difference is that

\[ \int dq_1 \frac{e^{-iq_1 \cdot \hat{x}}}{q_1^2 + \mu^2} \rightarrow \int dq_1 \frac{\alpha(m^2)dm^2}{q_1^2 + m^2} e^{-iq_1 \cdot \hat{x}} = 2\pi^2 \int_0^\infty m\alpha(m^2) Y_m(x)dm^2, \]

where the explicit form for the form factors has been substituted from equation (20). If the gradient operators are now applied to both sides of the correspondence given in equation (31), the following relations may easily be obtained:

\[ \mu^3 Y_\mu (x) \rightarrow \int_0^\infty m^3 \alpha(m^2) Y_m(x)dm^2. \]
and
\[ \mu^3 T_\mu(x) Y_\mu(x) \equiv \int_0^\infty m^3 a(m^2) \, T_m(x) \, Y_m(x) \, dm^2 . \] (33)

In the next chapter, the first order effects of \( w(x,y) \) in nuclear matter will be derived, but the important point to note now is that in deriving equation (30), the singular contact interaction terms with respect to the variables \( x \) and \( y \) have been explicitly removed from \( w(x,y) \).

The modified pion mass approach of BG is based on the definition of the effective interaction given in equation (16). An examination of equation (25) shows that if \( w \) is substituted in equation (16) the integration may immediately be done to give \( (2\pi)^3 \delta(q_1 - q_2) \). The integration may then be done, so that

\[ u(r) = \frac{f_N^2}{2\mu^2 \pi^2} \int \frac{dq_1 \cdot q_2 \cdot q}{(q^2 + \mu^2)^2} \, e^{-iq \cdot r} . \] (34)

where
\[ \delta_\mu^2 = -2\rho(A+B) q^2 H^2(q^2) , \] (35)

and \( \rho = N/\Omega \), the density of nuclear matter. Now if \( |\delta_\mu^2| < \mu^2 + q^2 \),

\[ \frac{\delta_\mu^2}{(q^2 + \mu^2)^2} \sim -\left[ \frac{1}{q^2 + \mu^2} - \frac{1}{q^2 + \mu^2} \right] , \] (36)

where \( \bar{\mu}^2 = \mu^2 + \delta_\mu^2 \). If equation (36) is substituted in equation (34), \( u(r) \) becomes
\[ u(r) = \frac{f_N^2}{2\mu^2 \pi^2} \left( \frac{1}{q^2 + \mu^2} - \frac{1}{q^2 + \mu^2} \right) e^{-i\mathbf{q} \cdot \mathbf{r}} \cdot \tag{37} \]

However, the OPEP (without form factors) is given by \((11)\)

\[ v(r) = \frac{f_N^2}{2\mu^2 \pi^2} \left( \frac{1}{q^2 + \mu^2} - \frac{1}{q^2 + \mu^2} \right) e^{-i\mathbf{q} \cdot \mathbf{r}} \cdot \tag{38} \]

Hence the effective interaction \( u(r) \) may be viewed as containing two parts, one the usual OPEP with pion mass \( \mu \), the other an OPEP with a modified pion mass \( \mu' \). This is the prescription used by BG to calculate the three-body effects, and its first order contribution will be discussed in the following chapter. Note however, that because of the integration over \( r_3 \), \( u(r) \) contains contact terms with respect to the variables \( r_1 - r_3 \) and \( r_2 - r_3 \), and so for this reason it is expected that the effects of \( u(r) \) will be somewhat different from those of \( w(x', y) \).

The alternative method to introducing the modified pion mass, and as will be seen in the next chapter the more desirable one, is to integrate equation (34) with respect to \( q \) and so find \( u(r) \) in coordinate space. Removing the singular contact terms according to the prescription given in equation (27), and substituting for the form factors from equation (20) gives

\[ u(r) = \frac{4C_\rho}{\pi \mu} \left( \frac{1}{q^2 + \mu^2} - \frac{1}{q^2 + \mu^2} \right) e^{-i\mathbf{q} \cdot \mathbf{r}} \cdot \tag{39} \]
The integrals are evaluated in Appendix A and the operator 
\((\sigma_1 \cdot V)(\sigma_2 \cdot V)\) applied. The final result is

\[
\nu(r) = C(\tau_1 \cdot \tau_2)[\sigma_1 \cdot \sigma_2 \, g_c(r) + S_{12}(r) \, g_t(r)],
\]

(40)

where

\[
C = \frac{4\pi \rho \sigma}{3\mu^3},
\]

\[
g_c(r) = c_1 Y_\mu(r) + c_2 E_\mu(r) + c_3 Y_\eta(r) + c_4 E_\eta(r),
\]

\[
g_t(r) = c_5 T_\mu(r) + c_2 (E_\mu(r) + Y_\mu(r)) + c_6 T_\eta(r) Y_\eta(r) + c_4 (E_\eta(r) + Y_\eta(r)),
\]

\[
E_m(r) = e^{-mr},
\]

and the constants \(c_1\) through \(c_6\) are given by equation (A.10). For comparison purposes and later use note that the OPEP is given by

\[
\nu(r) = B(\tau_1 \cdot \tau_2)[\sigma_1 \cdot \sigma_2 \, f_c(r) + S_{12}(r) \, f_t(r)],
\]

(41)

where \(B = f^2_{\text{max}}/3\), \(f_c(r) = Y_\mu(r)\), and \(f_t(r) = T_\mu(r) Y_\mu(r)\).

Using the form factors given in Table I and the constants given in Table II, the central and tensor parts, \(C_g_c(r)\) and \(C_g_t(r)\), of \(\nu(r)\) are plotted in figures 6 and 7, and compared with the central and tensor parts, \(B_f_c(r)\) and \(B_f_t(r)\), of OPEP. The introduction of form factors modifies the short range part of the interaction, and in the case of form factor III introduces an extreme suppression in the tensor part of \(\nu(r)\). Since the major contribution to the binding energy comes from the tensor part of the interaction,
Figure 6. The central part of the OPEP, $B.f_c(r)$, and the central part of the effective interaction, $C.g_c(r)$, for the form factors I, II, and III, plotted against $r$. 
Figure 7. The tensor part of the OPEP, $B.f_t(r)$, and the tensor part of the effective interaction $C.g_t(r)$, for the form factors I, II, and III, plotted against $r$. 
it is this suppression at short distances which characterizes the main effect of the form factors.
CHAPTER IV

THE FIRST ORDER CONTRIBUTIONS OF W AND U

Three different ways of describing the NNN interaction have been introduced in the previous chapter, and it is now desirable to understand what the important differences between these prescriptions are when each is applied to the calculation of the three-body effect in nuclear matter. The fact that the effective interaction $u(r)$ contains some singular contact terms which are absent in $w(x,y)$ has already been pointed out, and these are expected to lead to differences in the contributions of $u(r)$ and $w(x,y)$. In this chapter, the first order contribution of the NNN interaction will be examined in detail, and the differences obtained when it is calculated according to each of the above prescriptions discussed. In order to obtain the effects of the contact terms in $u(r)$, and to understand the modifications introduced by the form factors, the first order contribution of both $w$ and $u$ will first be calculated with $d$, the NN cut-off, taken to be zero. The results will then be generalized to the more realistic case in which $d$ is non-zero, and the contributions of $w$ and $u$ will be compared using the form factors given in Table I. The difficulty with the modified pion mass approach of BG when an NN cut-off is introduced will

**Table II.** Numerical values for constants used in calculating the first and second order contributions.
be discussed, and finally, the first order contribution of \( u \),
given by equation (40), will be obtained.

The prescription for introducing form factors into
\( w(x,y) \) has already been obtained (equations (32) and (33)),
and so \( <W>/N \) may first be calculated without form factors,
and their effect introduced when the calculation is complete.
BLN\(^6\) have calculated the first order effect for \( \Lambda \)-particle
in nuclear matter, and their result can be carried over
unaltered to the NNN case, with one exception. If the total
isospin \( I \), and its 3-component, \( I_3 \), are denoted by \( (I, I_3) \),
then for the \( \tau N \) system the \( i \)-spin is \( (1/2, I_3) \) or \( (3/2, I_3) \),
while for \( N^* \) it is \( (3/2, I_3) \). Hence for the reaction
\( \pi+N+N^* \), only four of the six initial states are coupled to
the final state. On the other hand, for the \( \pi\Lambda \) system, \( I=1 \)
only, and so all initial states are coupled to the final state.

This leads to the relation

\[
<W>_{NN}/N = \frac{4}{6} \cdot \left( \frac{C_p(\text{NN})}{C_p(\Lambda N)} \right) \cdot <W>_{\Lambda N} .
\]

Using equations (4) and (5) of reference (6),

\[
\frac{<W>}{N} = \frac{<W>_{NN}}{N} = \frac{C_p \rho^2}{4} \int D^2(k_F|\mathbf{x}-\mathbf{y}|) \{1 + (3 \cos^2 \theta_{xy} - 1) T_\mu(x) T_\mu(y) \} Y_\mu(x) Y_\mu(y) dx dy,
\]

where \( D(k_F r) = 3j_1(k_F r)/k_F r \), \( \cos \theta_{xy} = x \cdot y / xy \) (the geometry
is shown in figure 5c), and \( j_1 \) is a spherical Bessel function
of order one. Now define
\[ F(q) = \int \frac{d^2k_F}{(2\pi)^3} e^{-i\mathbf{q} \cdot \mathbf{r}}, \]  
(44)
so that
\[ D^2(k_Fr) = \frac{1}{(2\pi)^3} \int F(q) e^{i\mathbf{q} \cdot \mathbf{r}} d\mathbf{q}. \]  
(45)
Writing
\[ I_c = \mu^6 \int D^2(k_F |x-y|) Y_\mu(x) Y_\mu(y) dx \, dy, \]
it is shown in Appendix B that by using equation (45), \( I_c \)
may be reduced to
\[ I_c = 8\mu^4 \int_0^\infty dq \, q^2 \frac{F(q)}{(q^2+\mu^2)^2}. \]  
(46)
Similarly, if
\[ I_t = \mu^6 \int D^2(k_F |x-y|) (3\cos^2 \theta_{xy} - 1) Y_\mu(x) T_\mu(x) Y_\mu(y) T_\mu(y) dx \, dy, \]
\( I_t \) may be written in q-space as
\[ I_t = 16 \int_0^\infty dq \, q^6 \frac{F(q)}{(q^2+\mu^2)^2}. \]  
(47)
On collecting terms,
\[ \frac{<W>}{N} = \frac{2C_P^2}{\mu^6} \left[ \mu^4 \int_0^\infty dq \, q^2 \frac{F(q)}{(q^2+\mu^2)^2} + 2 \int_0^\infty dq \, q^6 \frac{F(q)}{(q^2+\mu^2)^2} \right]. \]  
(48)
Consider now the prescription given in equations (32)
and (33) for introducing form factors. Multiplying equation (32) by $x^2 j_0(qx)$, integrating over all $x$, and making use of equation (D1) gives

$$\frac{\mu^2}{(q^2+\mu^2)} + \int_0^\infty \text{dm} \frac{\alpha(m^2)}{q^2 + m^2}. \quad (49)$$

Similarly, on multiplying equation (33) by $x^2 j_2(qx)$, integrating over all $x$, and using equation (D2), the following correspondence is obtained:

$$\frac{1}{q^2+\mu^2} + \int_0^\infty \text{dm} \frac{\alpha(m^2)}{q^2 + m^2}. \quad (50)$$

Then when the effects of form factors are included, $\langle W \rangle/N$ becomes

$$\frac{\langle W \rangle}{N} = \frac{2C_0^2}{\mu^2} \int_0^\infty dq \frac{q^2}{F(q)} \left[ \int_0^\infty \text{dm} \frac{\alpha(m^2)}{q^2 + m^2} \right] + 2q^4 \left[ \int_0^\infty \frac{\text{dm} \alpha(m^2)}{q^2 + m^2} \right].$$

This expression may be rearranged slightly to give

$$\frac{\langle W \rangle}{N} = \frac{2C_0^2}{\mu^2} \int_0^\infty dq \frac{q^2}{F(q)} \left[ \int_0^\infty \text{dm} \frac{\alpha(m^2)}{q^2 + m^2} \right] + 2q^4 \left[ \int_0^\infty \frac{\alpha(m^2)\text{dm}^2}{q^2 + m^2} \right]. \quad (51)$$

The first order contribution of $u(r)$ is less complicated to derive. From equation (C1) only the exchange term
of equation (18) contributes, and upon doing the i-spin and spin sums using equations (C2) and (C4) \( \langle U \rangle / N \) becomes

\[
\frac{\langle U \rangle}{N} = -\frac{3f^2}{N\mu^2 \pi^2} \sum_{k_i, k_j} \langle k_i, k_j | u'(r) | k_j, k_i \rangle ,
\]

where

\[
u'(r) = \int dq \frac{\delta \mu q^2 e^{-iq \cdot r}}{(q^2 + \mu^2)^2} .
\]

Replacing the sums over \( k_i \) and \( k_j \) by integrals, and using the relation

\[
\int dk \ e^{i k \cdot r} = \frac{4\pi}{3} k_F^3 D(k_F r) ,
\]
equation 52 becomes

\[
\frac{\langle U \rangle}{N} = -\frac{3f^2}{N\mu^2 \pi^2} \int u'(r) D^2(k_F r) dr .
\]

In terms of \( F(q) \) and \( u'(q) = (2\pi)^3 \frac{\delta \mu q^2}{(q^2 + \mu^2)^2} \), the Fourier of \( u'(r) \), equation (53) gives

\[
\frac{\langle U \rangle}{N} = -\frac{3f^2}{N\mu^2 \pi^2} \int dq \frac{\delta \mu q^2 F(q)}{(q^2 + \mu^2)^2} .
\]

Substituting for \( \delta \mu^2 \) from equation (35), this expression may be rewritten as

\[
\frac{\langle U \rangle}{N} = \frac{6C_p \rho^2}{\mu^6} \int_0^\infty dq \int_0^\infty dm^2 \frac{\alpha(m^2)}{q^2 + m^2} F(q) .
\]
Comparing $\langle U \rangle/N$ with $\langle W \rangle/N$ given by equation (51), the two are seen to agree only if

$$\int_0^\infty dm^2 \alpha(m^2) = 0. \quad (56)$$

Thus, provided that the spectral function, $\alpha(m^2)$, is chosen in such a way that equation (56) is satisfied, the contact terms appearing in $\langle U \rangle/N$ will be of no importance. If the spectral function given in equation (21) is substituted in equation (56), the condition $\xi = 0$ is obtained. For one of the form factors used in later calculations, this condition will be satisfied, while for the other $\xi = 0.28$.

In order to ascertain how sensitive the difference between $\langle W \rangle/N$ and $\langle U \rangle/N$ is to the value of $\xi$, both quantities were calculated for the more realistic case of non-zero $d$. When a cut-off is introduced, the expression corresponding to equation (51) may be found by substituting for $D^2(k_Fr)$ the quantity $D^2(k_Fr) \theta(r-d)$, so that $F(q)$ is replaced by $\tilde{F}(q)$, where

$$\tilde{F}(q) = F(q) - 4\pi \int_0^d D^2(k_Fr) j_0(qr)r^2dr. \quad (57)$$

Details of the evaluation of $\langle W \rangle/N$ are given in Appendix F, and the results are compared with the contribution of $\langle U \rangle/N$ in Table III. For form factor III the results are identical, as equation (56) would predict. Perhaps more important is the fact that the results are very nearly the same for form

Table III. Comparison of the first order contributions of the three-body interaction W, and the effective interaction U. All energies are in MeV.
factor II, where $\xi = 0.28$. This result will lend support to the assumption that even for form factor II the delta-functions in $u$ give a negligible contribution, and so $u$ may be used to calculate the second order three-body contribution to nuclear matter.

BG calculate the first order contribution of $u$ by making use of equation (37), according to which

$$\frac{<U>}{N} = \frac{<V(\mu=\mu) >}{N} - \frac{<V(\mu=\bar{\mu}) >}{N}$$

(58)

However, on comparing equations (34) and (38), the OPEP is seen to be related to $u(r)$ through the correspondence

$$\frac{\delta \mu^2}{q^2+\mu^2} \rightarrow -\frac{1}{q^2+\mu^2},$$

which when substituted in equation (54) gives

$$\frac{<V>}{N} = \frac{3f^2_{10}}{16\pi^2\mu^2} \int dq \frac{q^2\tilde{F}(q)}{q^2+\mu^2}.$$  

(59)

Then if no NN cut-off is introduced, the three-body effects can be obtained by modifying the pion mass in the OPEP contribution as equation (58) indicates, and this is the prescription given by BG. However, when an NN cut-off is introduced, the result is more complicated because of the $q$ dependence of $\tilde{\mu}$. BG make the error of replacing $1/(q^2+\mu^2)$ by the Fourier transform of the cut-off Yukawa, and so in effect have neglected the momentum dependence of $\tilde{\mu}$. Instead,
what should be done is to find the potential corresponding to $1/(q^2 + \mu^2)$ in coordinate space, cut it off at $r=d$, and then find the Fourier transform of this cutoff potential. However, because of mathematical difficulties in carrying out this procedure, and because the simple result given by equation (58) will no longer hold, it does not seem useful to pursue this method any further.

Consider now the first order contribution of the effective interaction, $u(r)$, given by equation (40). Because of equation (C1) only the central part contributes, and using techniques exactly similar to those used in obtaining equation (54), $<U>/N$ becomes

$$
\frac{<U>}{N} = -\frac{9}{4} \frac{C_0}{\pi} \int g_c(q) F(q) q^2 dq , \quad (60)
$$

where

$$
g_c(q) = \int_d^\infty j_0(qr) g_c(r)r^2 dr .
$$

There is however, one important difference between equations (54) and (60) which should be noted at this point. In deriving the effective interaction in coordinate space, the contact terms with respect to the variable $r$ have been explicitly removed, while in equation (54) the contribution of such contact terms still remain. Of course, if an NN cut-off is introduced, equations (54) and (60) will give identical results, and for convenience equation (60) will
be used throughout in the first order calculation of $u$. The contribution of $v$ is given by a similar expression which can be found by setting $C$ to $B$ and $g_c(r)$ to $f_c(r)$ in equation (60), and when equation (F1) for $F(q)$ is substituted in equation (60), the integral may be done numerically to obtain both $<U>/N$ and $<V>/N$.

The examination in this chapter of the first order contribution of the three-body force to nuclear matter has indicated that the effective interaction, $u(r)$, describes quite adequately the first order three-body effects involving the single exchange terms, and on this basis $u$ will be used in the following chapter to calculate the second order three-body effects.
CHAPTER V

THE SECOND ORDER CONTRIBUTION OF U

In the previous chapter, the first order contributions of \( w \) and \( u \) were compared, in order to see how the form factors modify the short range part of the interaction. The conclusion was reached that provided the form factors at least approximately satisfied equation (56), the effect of the spurious contact terms in \( u \) would be negligible. The same conclusion will be assumed to hold for the second order calculation, and so \( u \) rather than \( w \) may be used to calculate the second order contribution of the three-body interaction. Because of the similarity in form between \( u \) and \( v \), the equations obtained for the calculation of \( u \) may easily be modified to permit a second order calculation of the OPEP contribution, and so the two and three-body results may easily be compared. To show how the calculation proceeds, the contribution of the cross term, \( <U_{1/b} V> \), will be calculated, and the method of obtaining the OPEP contribution, \( <V_{1/b} V> \), and the pure three-body term, \( <U_{1/b} U> \), from this result will be given.

From equation (17) the direct contribution of \( <U_{1/b} V> \) is

\[
\frac{\Delta E^{(2)}}{N} \text{(C.T.)} = \frac{1}{2N} \sum_i \sum_{i',j'} \sum_{i,j} <i|v|i'j><i'j'|u|ij> \epsilon_i + \epsilon_{i'} - \epsilon_j - \epsilon_{j'}
\]

(61)
The single particle energies, $\varepsilon_y$, will be taken to be the free particle kinetic energy, $\hbar^2 k_y^2/2M$, where $M$ is the nucleon mass. Then

$$\varepsilon_i + \varepsilon_j - \varepsilon_i' - \varepsilon_j' = \frac{\hbar^2}{2M} (k_i^2 + k_j^2 - k_i'^2 - k_j'^2) .$$  \hspace{1cm} (62)$$

Momentum conservation in nuclear matter requires that

$$q \equiv k_i' - k_i = k_j' - k_j ,$$  \hspace{1cm} (63)

so that equation (62) simplifies to

$$\varepsilon_i + \varepsilon_j - \varepsilon_i' - \varepsilon_j' = -\frac{\hbar^2}{M} q_i \cdot (q + k_i - k_i') .$$  \hspace{1cm} (64)

Because of the condition given by equation (63), the four sums over momenta appearing in equation (61) reduces to three sums over the variables $k_i$, $k_j$ and $q$, where the sums are restricted so that

$$|k_i| < k_F , \quad |k_j| < k_F ,$$  \hspace{1cm} (65)

$$|q + k_i| > k_F , \quad |k_j - q| > k_F .$$

According to equations (C13) and (C14) any terms linear in $S_{12}(\hat{r})$ cannot contribute to $\Delta E_d^{(2)}(C.T.)/N$, and so equation (61) reduces to two terms, one involving only the central parts of $v$ and $u$, the other involving only the tensor parts. According to the results given in Appendix C, the $i$-spin and spin sums for the central contribution will give a factor of $12 \times 12$, while the $i$-spin and spin sums of the tensor contribution will give a factor of $12 \times 24$. With these
substitutions equation (61) may be written as

\[
\frac{\Delta E^{(2)}_d}{N}(\text{C.T.}) = -\frac{B.C.}{2N} \frac{M}{k^2} (4\pi)^2 \sum_{k_i,k_j,q}^{\infty} \frac{[144f_c(q)g_c(q) + 288f_t(q)g_t(q)]}{q \cdot (q + k_i - k_j)}
\]

(66)

where the \(j_0\) and \(j_2\) transforms have been defined and evaluated in Appendix D. Using the relations

\[
\frac{\Sigma}{k} \rightarrow \frac{\Omega}{(2\pi)^3} \int \frac{dk_i}{q \cdot (q + k_i - k_j)} , \text{ as } \Omega \rightarrow \infty , \quad \text{(67)}
\]

and

\[
\int \frac{dk_i dk_j}{q \cdot (q + k_i - k_j)} = \frac{4\pi^2 k_F^5}{15q} \frac{P(q/2k_F)}{15q} \quad \text{(68)}
\]

discussed in Appendix E, equation (66) simplifies to

\[
\frac{\Delta E^{(2)}_d}{N}(\text{C.T.}) = -\frac{18}{5\pi^2} \frac{M}{k^2} B.C. k_F^2 \int dq \left[ f_c(q)g_c(q) + 2f_t(q)g_t(q) \right] \]

(69)

where the constants B and C have been defined by equations (40) and (41). Since the function \(P\) is known analytically (equation (E2)) this integral may be evaluated numerically, and a value for \(\Delta E^{(2)}_d(\text{C.T.})/N\) may be obtained.

The direct OPEP contribution, \(\Delta E^{(2)}_d(\text{OPEP})/N\), may now easily be found by setting \(C\) to \(B\), \(g_c\) to \(f_c\), and \(g_t\) to \(f_t\) in equation (69). Hence

\[
\frac{\Delta E^{(2)}_d}{N}(\text{OPEP}) = -\frac{18}{5\pi^2} \frac{M}{k^2} B^2 k_F^2 \int dq \left[ f_c^2(q) + 2f_t^2(q) \right] . \quad \text{(70)}
\]
Similarly, the pure three-body contribution, $\Delta E_d^{(2)}(T.B.)/N$, may be found by setting $B$ to $C$, $f_c$ to $g_c$, and $f_t$ to $g_t$ to obtain

$$\Delta E_d^{(2)}(T.B.)/N = \frac{18}{5\pi^2} \frac{M}{\hbar^2} C^2 k_F^2 \int_0^\infty dq \, P(q/2k_F) [g_c^2(q) + 2g_t^2(q)].$$

(71)

The exchange contribution of $<U \, l/b \, V>$ is

$$\Delta E_{\text{ex}}^{(2)}(C.T.) = -\frac{1}{2N} \sum_{i,j,i',j'} \frac{<ij|v|i'j'> <i'j'|v|ij>}{\epsilon_i + \epsilon_j - \epsilon_{i'} - \epsilon_{j'}}.$$  

(72)

Making use of the spin sums given in Appendix C, evaluation proceeds as for the direct term, so that

$$\Delta E_{\text{ex}}^{(2)}(C.T.) = \frac{B \cdot C}{2N} \frac{M(4\pi)^2}{\hbar^2} \sum_{k_i, k_j, q} \frac{[36f_c(q)g_c(s) - 144g_2(\cos \theta s) f_t(q) g_t(s)]}{q \cdot (q + k_i - k_j)}.$$  

(73)

where $s = q + k_i - k_j$. Replacing the sums by integrals using equation (67), and using the generalized Euler functions $G_0$ and $G_2$, discussed in Appendix E and tabulated in reference (13), equation (73) becomes

$$\Delta E_{\text{ex}}^{(2)}(C.T.) = \frac{27}{2\pi^3} \frac{B \cdot C}{2N} \frac{M}{\hbar^2} \int q dq \int s ds \left[ G_0(q/k_F, s/k_F) f_c(q) g_c(s) - 4G_2(q/k_F, s/k_F) f_t(q) g_t(s) \right].$$  

(74)

where $q$ runs from 0 to $\infty$, and $v$ runs from $\max(0, q-2k_F)$ to $q + 2k_F$. 
The same correspondence as was used with the direct contribution may be used to find $\Delta E^{(2)}_{\text{ex}}(\text{OPEP})/N$ and $\Delta E^{(2)}_{\text{ex}}(\text{T.B.})/N$, with the results

$$\Delta E^{(2)}_{\text{ex}}(\text{OPEP}) = \frac{27}{2\pi^3} B^2 \frac{M}{\hbar^2} \int \frac{q dq}{2^9} \int \frac{ds ds}{4\pi^2} \left[ G_0 f_c(q) f_c(s) - 4G_2 f_t(q) f_t(s) \right],$$

(75)

and

$$\Delta E^{(2)}_{\text{ex}}(\text{T.B.}) = \frac{27}{2\pi^3} c^2 \frac{M}{\hbar^2} \int \frac{q dq}{2^9} \int \frac{ds ds}{4\pi^2} \left[ G_0 g_c(q) g_c(s) - 4G_2 g_t(q) g_t(s) \right],$$

(76)

where it is understood that $G_0$ and $G_2$ have the same arguments as in equation (74).

All the required first and second order results have now been obtained. In Appendix F some of the details concerned with the numerical evaluation of these contributions has been discussed, and in the following chapter the various results given in Tables IV and V will be discussed, with a view to determining the importance of the three-body force in nuclear matter.
CHAPTER VI

DISCUSSION OF RESULTS

In Chapter IV the first order contributions of $w$ and $u$ were considered in detail, and the effects of the form factors on the short-range part of the effective interaction, $u$, discussed. Assuming that the three-body interaction could accurately be described by $u(r)$, the second order contributions were derived in Chapter V. Using the parameters given in Table II and the integration methods discussed in Appendix F, the first and second order contributions of the OPEP, $v$, and the effective interaction, $u$, have been calculated and tabulated in Tables IV and V. The contributions for various values of the cut-off have been given, although the most realistic value is probably for $d=1 F$, and in the following discussion all results taken from Table IV and V will refer to the column in which $d=1 F$.

Although the two-body contributions given in Table IV are not of primary importance here, a brief discussion of these results will point out several facts which also hold for the three-body contributions. The first order contribution, $\Delta E^{(1)}(\text{OPEP})/N$, is seen to be small -- about 3 MeV attraction, while the second order contribution is almost 20 MeV attraction. This would seem to indicate that the perturbation

**Table IV.** First and second order OPEP contributions. The direct and exchange contributions are shown separately, and the total contribution, $\Delta E(v)/N$ is given. All energies are in MeV.
series is not converging, and that higher order terms should be considered. However, as was pointed out in Chapter IV only the central part of the OPEP contributes is first order, while the tensor part gives a large contribution in second order, and so it is possible that by the third order the contributions will have become small. Third order calculations have been performed using the OPEP and this possibility has been confirmed.\(^{(16)}\)

The total OPEP contribution, \(\Delta E(v)/N\), is seen to be about 23 MeV attraction, which when combined with the average kinetic energy per particle of 23 MeV gives a net binding energy per particle of approximately zero. However, at \(d=0.8\)F, the potential energy contribution is now sufficient to give a binding energy of approximately 17 MeV per particle, and so the contribution is very sensitive to the value of the NN cut-off. The result will also be seen to hold for the contribution of the effective interaction, and BLN, in their consideration of the first order contribution of \(w\), have reached a similar conclusion.

Turning now to the effective interaction contributions given in Table V it is seen that for a realistic form factor (either II or III) the first order contribution of \(u\) ranges from 0.1 MeV to 0.5 MeV repulsion. BG in using their modified pion mass approach concluded that the first order contribution of the effective interaction is approximately 1.2 MeV repulsion. The reason for this disagreement can be

Table V. First and second order contributions of the effective interaction u. The total contribution, \( \eta(E)/N \), is given, as well as the ratio, \( \eta(E)/\Delta E(v) \), of the three-body and two-body contributions. All energies are in MeV.
traced to the error in BG's method of imposing on NN cut-off, already discussed in Chapter IV. In second order, the total contribution of \( u \) is approximately 6 MeV additional attraction, so that altogether the total three-body contribution, \( \Delta E(u)/N \), would appear to be approximately 5.5 to 6 MeV of additional binding to nuclear matter. When compared with the OPEP value of 23 MeV, the three-body force is seen to contribute 20% to 25% of the two-body contribution to the potential energy per particle.

From equation (42), a partial estimation of the contribution of the three-body \( \Lambda NN \) interaction to the binding energy of a \( \Lambda \)-particle in nuclear matter can be obtained, using the results given in Table V. The first order contribution, \( \Delta E^{(1)}(\Lambda NN) \), can be unambiguously determined, and is given in the first row of Table VI. In second order, the term \( <U_{\Lambda NN} 1/b U_{\Lambda NN}> \), where the subscripts indicate explicitly the origin of the effective interaction, will give no contribution, since for a \( \Lambda \)-particle it will proportional to \( 1/N \). However, the term \( <V_{NN} 1/b U_{\Lambda NN}> \) will contribute, and its contribution is given in Table VI as \( \Delta E^{(2)}(\Lambda NN) \). The total contribution, \( \Delta E(\Lambda NN) \), is seen to be unrealistically large, for the binding energy of a \( \Lambda \)-particle in nuclear matter is believed to be approximately 30 MeV\(^6\) (note that for a \( \Lambda \)-particle in nuclear matter the kinetic energy is zero), and so this result would indicate that the three-body force gives rise to almost all of the binding energy. However, it is
Table VI. First and second order contributions of the three-body $\Lambda NN$ force to $\Lambda$-particle binding in nuclear matter. All energies are in MeV.
well known that the two-body $\Delta N$ forces alone tend to give an overestimate of the $\Lambda$-particle binding, and in fact the three-body forces were originally introduced as a possible mechanism to suppress the two-body effects.

The reasons for the unrealistically large values of $\Delta E(\Lambda NN)$ are not clear. One possibility is that the second order term given by $<V_{\Delta N} \frac{1}{b} W_{\Lambda NN}>$ may give a sizeable contribution and so perhaps cancel some or all of the contribution due to $<V_{NN} \frac{1}{b} W_{\Lambda NN}>$. This term cannot be calculated as readily as the other second order terms, since the $\Lambda$-particle will no longer be a spectator, and so an effective interaction cannot be determined. Another alternative is that the two-pion exchange process may not be the only one which gives a sizeable contribution to the three-body force, and for example the double exchange of the $\sigma$-meson has been suggested as a possible contributor \(^{23}\).

There is also some question as to whether the use of form factors as opposed to the introduction of explicit cut-offs in the variables $x$ and $y$ gives a realistic method for calculating the contributions of the three-body force. When the first order contributions given in Table VI are compared with those given by BLN in reference 6, the agreement is only qualitative in nature. Both methods of calculation predict that in first order the three-body force gives rise to a slight repulsion which is very sensitive to the NN cut-off, but the quantitative agreement is very poor. This indicates that the method of calculation used here is quite ambiguous, and
that if explicit cut-offs had been introduced in the variables \( x \) and \( y \), a very different second order contribution might have been obtained.

No further examination of these questions will be undertaken here. However, the several ambiguities in the calculation of the three-body contributions both to nuclear matter and to \( \Lambda \)-particle binding should be noted, and all numerical values should be regarded with suspicion until more detailed calculations can be performed.

In conclusion, a brief discussion of the main assumptions which have gone into the calculations of the results summarized in Tables IV through VI will be given.

The derivation of the three-body force has been carried out in the static limit, and although the exchanged pions cannot strictly be of zero energy, the main contribution to the first order energy comes from a region near \( q=1F^{-1} \), while in second order the corresponding value is \( q=2F^{-1} \). Because the main contribution comes from such small \( q \) values, the assumption of the static limit would appear justified. However, unless a more precise three-body interaction is derived, and the calculation repeated with it, no definite conclusion can be reached.

A second assumption concerned with the three-body force is that the TPE process is the main contributor to the three-body interaction. Higher order processes, such as the exchange of more than two, or of heavier mesons can be
expected to be of some importance, and some such processes have been considered by other workers\(^{(1,9)}\). However, in the same way that the OPEP tail can reproduce approximately the effects of the two-nucleon force, it is perhaps reasonable to suppose that the tail of the effective interaction due to the TPE process can reproduce reasonably well the three-body effects.

In connection with the perturbation expansion, two basic assumptions have been made. In the first place, the series has been truncated after second order, on the assumption that higher order terms are not important. Because the tensor contribution in second order has led to a value very much larger than the first order contribution, this assumption would seem to be quite unjustified. However, as has already been mentioned, the effects of the third order terms have been calculated for the OPEP, and the conclusion was reached that third and higher order terms are indeed quite small. Because the effective interaction is weaker than the OPEP (figures 6 and 7) a similar convergence can be expected for this case as well.

The second assumption concerned with the perturbation series, and one which is less easily justified, is that only single exchange terms contribute. The double exchange terms have been calculated in first order for the three-body interaction \(w^{(1,9)}\), and found to be approximately 12% of the single exchange term. In the results presented in Table V,
the assumption has been made that the single exchange terms also dominate the second order contribution, although it would appear possible that the great number of double exchange terms which contribute in second order may combine to give a contribution comparable in size to that of the single exchange terms. It is worth noting, however, that for the $\Lambda NN$ interaction, the first order term and any second order terms involving $V_{NN}$ can only have contributions from the single-exchange terms, because in these cases the $\Lambda$-particle is always a spectator.

The results of the calculations presented here indicate that the three-body force can contribute approximately 6 MeV additional attraction in nuclear matter. This number is not meant to be a precise estimation of the three-body effects, for many ambiguities still remain in the calculation. In particular the results are sensitive to the form of the two-body interaction, and clearly a more realistic form of the two-nucleon force could be used. Also, the NN cut-off is a very important, but quite arbitrary parameter, and a calculation which avoided the introduction of a cut-off would be desirable. However, this would require a detailed knowledge of not only the two-body, but also the three-body force for arbitrarily small distances. Such a detailed description of the three-body force is not available at this time, either from a theoretical or experimental point of view.
APPENDIX A

SOME RESULTS REQUIRED IN THE EVALUATION OF W AND U

The following integrals will be of use in calculating the effective interaction in coordinate space:

\[
\int \frac{dq}{q^2 + \mu^2} \frac{e^{-iq \cdot r}}{(q^2 + \eta^2)} = \frac{4\pi}{r} \int_0^\infty \frac{q^3 \sin qr dq}{(q^2 + \mu^2)(q^2 + \eta^2)} = 2\pi^2 \frac{[\mu^3 Y_\mu(r) - \eta^3 Y_\eta(r)]}{\mu^2 - \eta^2}
\]

(A1)

where use has been made of no. 5 p. 63 and no. 25 p. 66 of the Bateman tables (14). On setting \( \eta = 0 \) the Fourier transform of the Yukawa function is obtained:

\[
\left\{ \begin{array}{l}
\int \frac{dq}{q^2 + \mu^2} e^{-iq \cdot r} = 2\pi^2 \mu Y_\mu(r) . \\
\end{array} \right.
\]

(A2)

Using no. 39 p. 68 of reference (14) the following result may easily be obtained:

\[
\left\{ \begin{array}{l}
\int \frac{dq}{(q^2 + \mu^2)^2} e^{-iq \cdot r} = \frac{4\pi}{r} \int_0^\infty \frac{q^3 \sin qr dq}{(q^2 + \mu^2)^2} = \pi^2 \mu [2Y_\mu(r) - E_\mu(r)] . \\
\end{array} \right.
\]

(A3)

Finally, the following two integrals will be required in evaluating the first order contribution of \( W \):

\[
\left\{ \begin{array}{l}
\int \frac{dq}{(q^2 + \mu^2)^2} e^{-iq \cdot r} = \frac{\pi^2}{\mu} E_\mu(r) , \\
\end{array} \right.
\]

(A4)
using no. 39 p. 68 of the Bateman tables, and

\[ \int \frac{dq \ e^{-iq \cdot \mathbf{r}}}{(q^2 + \mu^2)(q^2 + \eta^2)} = 2\pi^2 \frac{[\eta Y_n(r) - \mu Y_\mu(r)]}{\mu^2 - \eta^2}, \]

(A5)

using no. 25 p. 66.

The effect of the operator \((\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla)\) on an arbitrary function of \(r\), say \(f(r)\), will be required. Now

\[ (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla)f(r) = \sigma_1 \cdot \nabla \{ (\sigma_2 \cdot \nabla) \left( \frac{1}{r} \frac{df(r)}{dr} \right) \}, \]

and making use of the relations \(\nabla(\sigma_2 \cdot \nabla) = \sigma_2\) and

\[ \nabla \left( \frac{1}{r} \frac{df}{dr} \right) = \frac{1}{r^2} \left( \frac{d^2 f}{dr^2} - \frac{1}{r} \frac{df}{dr} \right), \]

this expression gives

\[ (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla)f(r) = (\sigma_1 \cdot \sigma_2) \left( \frac{1}{r} \frac{df(r)}{dr} \right) + (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla) \left( \frac{1}{r^2} \frac{d^2 f}{dr^2} - \frac{1}{r} \frac{df}{dr} \right). \]

(A6)

If \(f(r) = Y_\mu(r)\), equation (A6) gives

\[ (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla)Y_\mu(r) = \frac{\mu^2}{3} [\sigma_1 \cdot \sigma_2 + S_{12}(\hat{r}) \cdot T_\mu(r)] Y_\mu(r), \]

(A7)

while for \(f(r) = E_\mu(r)\),

\[ (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla)E_\mu(r) = \frac{\mu^2}{3} [\sigma_1 \cdot \sigma_2 + S_{12}(\hat{r}) \cdot \hat{E}_\mu(r)] + \frac{\mu^2}{3} [-2\sigma_1 \cdot \sigma_2 + S_{12}(\hat{r}) \cdot Y_\mu(r)]. \]

(A8)

From equation (39) the effective interaction is given by

\[ u(r) = \frac{4\pi}{\mu} \int \frac{dq}{6} \left( \tau_1 \cdot \tau_2 \right) (\sigma_1 \cdot \nabla)(\sigma_2 \cdot \nabla) \left( \frac{1}{q^2 + \mu^2} \right), \]
\[ - \frac{2(1-\xi)}{(q^2 + \mu^2)(q^2 + \eta^2)} + \frac{(1-\xi)^2}{(q^2 + \eta^2)^2} e^{-i\xi \cdot r} \quad \text{(A9)} \]

Using equations (A1) and (A3) the integrals may be done to give

\[ \pi^2 \left[ (2\mu - 4\frac{(1-\xi)\mu^3}{\mu^2 - \eta^2}) Y_\mu(r) - \mu E_\mu(r) + (2(1-\xi)^2 \eta + 4\frac{(1-\xi)\eta^3}{\mu^2 - \eta^2}) Y_\eta(r) \right. \]

\[ \left. - (1-\xi)^2 \eta E_\eta(r) \right] . \]

Applying equations (A7) and (A8) \( u \) may be written as in equation (40), with \( c_1 \) through \( c_6 \) given by

\[ c_1 = 4 - 4(1-\xi) \frac{\mu^2}{(\mu^2 - \eta^2)} , \]

\[ c_2 = -1 , \]

\[ c_3 = 4(1-\xi)^2 (\eta/\mu)^3 + 4(1-\xi) \eta^2 (\eta/\mu)^3 / (\mu^2 - \eta^2) , \]

\[ c_4 = -(1-\xi)^2 (\eta/\mu)^3 , \]

\[ c_5 = 2 - 4(1-\xi) \frac{\mu^2}{(\mu^2 - \eta^2)} , \]

\[ c_6 = 2(1-\xi)^2 (\eta/\mu)^3 + 4(1-\xi) \eta^2 (\eta/\mu)^3 / (\mu^2 - \eta^2) . \quad \text{(A10)} \]
APPENDIX B

SOME RESULTS REQUIRED IN OBTAINING \( \langle w \rangle / N \)

On substituting for \( D^2(k_F|x-y|) \) in terms of \( F(q) \) in \( I_c \) one obtains

\[
I_c = \frac{\mu^6}{(2\pi)^3} \int dq \ F(q) \left( \int Y_\mu(x) e^{iq\cdot x} \ dx \right)^2.
\]

But

\[
\int Y_\mu(x) e^{iq\cdot x} \ dx = 4\pi f_c(q),
\]

where \( f_c(q) \) is given by equation (D1), and so

\[
I_c = 8\mu^4 \int dq \ \frac{a^2 F(q)}{(q^2 + \mu^2)^2}.
\] (B1)

Similarly, when \( D^2 \) is replaced by its Fourier transform in \( I_t \) one obtains

\[
I_t = \frac{\mu^6}{(2\pi)^3} \int dq \ F(q) \int dx dy \ e^{iq\cdot(x-y)} (3\cos^2 \theta_{xy} - 1) Y_\mu(x) T_\mu(x) Y_\mu(y) T_\mu(y).
\] (B2)

Now

\[
3 \cos^2 \theta_{xy} - 1 = \frac{8\pi}{5} \sum_m \ Y^*_m(x) Y_{2m}(y),
\] (B3)

and

\[
e^{iq\cdot x} = 4\pi \sum_{\ell, \eta} \ Y^*_\eta(\hat{q}) \ Y_{2\ell}(x) j_\ell(qx),
\] (B4)
with a similar expression for $e^{-i\mathbf{q} \cdot \mathbf{y}}$. When equations (B3) and (B4) are substituted in equation (B2), the angular integrations over $x$, $y$ and $q$ may be done, so that

$$I_t = 16\mu^2 \int dq \, q^2 \, F(q) \left( \int_0^\infty j_2(qx) \, T_\mu(x) \, Y_\mu(x) x^2 dx \right)^2. \quad (B5)$$

Substituting for the integral over $x$ from equation (D2), $I_t$ becomes

$$I_t = 16 \int_0^\infty dq \, \frac{q^6 F(q)}{(q^2 + \mu^2)^2}. \quad (B6)$$
APPENDIX C

EVALUATION OF THE FIRST AND SECOND ORDER SPIN SUMS

I. First Order

The matrix elements for the central contribution are of the form \( \langle ij | (\tau_1 \cdot \tau_2)(\sigma_1 \cdot \sigma_2) \ k(r) | ij \rangle \) and \( \langle ij | (\tau_1 \cdot \tau_2)(\sigma_1 \cdot \sigma_2) \ k(r) | ji \rangle \), while for the tensor contribution they are \( \langle ij | (\tau_1 \cdot \tau_2) \ S_{12}(r) \ k(r) | ij \rangle \) and \( \langle ij | (\tau_1 \cdot \tau_2) \ S_{12}(r) \ k(r) | ji \rangle \), where \( k(r) \) stands for any of the radial functions appearing in the OPEP or the effective interaction. The state labels \( i \) and \( j \) include all the quantum numbers necessary to specify the single particle states, so that, for example, \( \mid i \rangle = \mid \tau_i m_i k_i \rangle \) where \( \tau_i \) is the 3-component of the i-spin, \( m_i \) the z-component of the spin, and \( k_i \) the linear momentum, all with reference to the \( i \)th state. The first order contribution requires a sum over all occupied states, and because of the nature of the matrix elements, the i-spin and spin sums may be separated from the sum over momentum, and done individually.

The direct i-spin sum is

\[
\sum_{\tau_i,\tau_j} \langle \tau_i \tau_j | \tau_1 \cdot \tau_2 | \tau_i \tau_j \rangle = \sum_{\tau_i,\tau_j} \langle \tau_i \tau_j | 2P^\tau_{12} - 1 | \tau_i \tau_j \rangle ,
\]

where \( P^\tau \) is the i-spin exchange operator\(^{15}\). The sum is now easily evaluated to give

\[
2 \sum_{\tau_i} - \sum_{\tau_i,\tau_j} = 0 . \tag{C1}
\]
A similar result holds for the direct spin sum. The exchange \( i \)-spin sum is

\[
\sum_{i,j} \langle \tau_i \tau_j | 2p_{12}^{-1} | \tau_j \tau_i \rangle = 6 ,
\]

with a similar result for the exchange spin sum.

For the tensor contribution, the spin sum may be separated from the radial part by taking \( \hat{r} \) as the quantization axis to give

\[
\sum_{m_i, m_j} <m_i, m_j | 3\sigma_z^{(1)} \sigma_z^{(2)} - \sigma_z \cdot \sigma_z | m_i, m_j > = 0 .
\]

Similarly the exchange spin sum gives zero, so that to first order only the central part of the potential contributes.

Finally, the evaluation of the first order contribution of \( u \) as given by equation (52) requires the following relation:

\[
\sum_{m_i, m_j} <m_i, m_j | (\sigma_1 \cdot q) (\sigma_2 \cdot q) | m_j, m_i > = 2q^2 .
\]

This may be proven by taking \( \hat{q} \) as the quantization axis to give

\[
\sum_{m_i, m_j} <m_i, m_j | \sigma_z^{(1)} \sigma_z^{(2)} | m_j, m_i > .
\]

The sums are now easily performed to give equation (C4).
II. Second Order

The i-spin sum for the central direct contribution is

$$\sum_{\tau_i, \tau_j} \sum_{\tau_i', \tau_j'} <\tau_i \tau_j | (\tau_{i1} \cdot \tau_{i2}) | \tau_i' \tau_j'> <\tau_i' \tau_j' | (\tau_{i1} \cdot \tau_{i2}) | \tau_i \tau_j> .$$

Closure may be used to reduce this sum to

$$\sum_{\tau_i, \tau_j} <\tau_i \tau_j | (2P_{i2}^\tau - 1)^2 | \tau_i \tau_j> = 12 . \quad (C5)$$

The central exchange i-spin sum is

$$\sum_{\tau_i, \tau_j} <\tau_i \tau_j | (2P_{i2}^\tau - 1)^2 | \tau_j \tau_i> = -6 . \quad (C6)$$

Similar results hold for the direct and exchange spin sums.

The spin sums involving the operator $S_{12}(\hat{r})$ may best be evaluated by first expressing $S_{12}$ in q-space and then performing the summations. A typical matrix element appearing in the second order contribution can be expressed as follows:

$$<k_i k_j | S_{12}(\hat{r}) \ k(\hat{r}) | k_i' k_j'> = \frac{1}{\Omega} \int e^{iq \cdot r} S_{12}(\hat{r}) \ k(\hat{r}) dr \ , \quad (C7)$$

where $q$ is given by equation (63). Using equation (B4) and the relation

$$S_{12}(\hat{r}) = \sum_{\mu} \sum_{\mu_{12}} \sum_{\mu_{12}} ^* \chi_{12-\mu}(\hat{r}) , \quad (C8)$$
where $T^2_{-\mu}$ is a second rank tensor involving only the spin variables, equation (C7) becomes, on performing the angular integration over $r$,

\[<k_i^j|S_{12}(\hat{r}) k(r)|k_i^j> = \frac{-4\pi}{\Omega} S_{12}(\hat{q}) k_2(q), \quad \text{(C9)}\]

where

\[k_2(q) = \int_0^\infty j_2(qr) k(r)r^2dr. \quad \text{(C10)}\]

A similar expression holds for the exchange matrix element, with $q$ replaced everywhere by $\omega = q+k_i-k_j$.

Consider now the direct spin sum given by

\[\sum_{m_i,m_j} |S_{12}(\hat{q})|^{m_i,m_j} \cdot |S_{12}(\hat{q})|^{m_i,m_j}, \quad \text{(C11)}\]

where closure has been used. On writing $S_{12}(\hat{q})$ as in equation (C3) the sums may readily be performed to give

\[\sum_{m_i,m_j} |S_{12}(\hat{q})|^{m_i,m_j} = 24. \quad \text{(C11)}\]

The exchange sum is given by

\[\sum_{m_i,m_j} |S_{12}(\hat{q}) S_{12}(\hat{s})|^{m_i,m_j}, \quad \text{(C12)}\]

This expression is slightly more difficult to evaluate because of the appearance of both $\hat{s}$ and $\hat{q}$ in the matrix
elements. However, by again taking $q$ as the quantization axis and expressing $(\sigma_{l1}.s)(\sigma_{l2}.s)$ in terms of it, the sum may be evaluated in a straightforward but tedious manner to give

$$\sum_{m_i,m_j} <m_i,m_j|S_{12}(q)S_{12}(x)|m_j,m_i> = 24 P_2(\cos \theta_{sq}) . \quad (C12)$$

A final result which will prove useful is

$$\sum_{m_i,m_j} <m_i,m_j|S_{12}(\hat{q})(\sigma_{l1}.\sigma_{l2})|m_i,m_j> = 0 . \quad (C13)$$

This may be proven by taking $q$ as the quantization axis, and replacing $\sigma_{l1}.\sigma_{l2}$ by $2P_{12}^\sigma - 1$ to obtain

$$3 \sum_{m_i,m_j} \{2|m_i,m_i|\sigma_z(1)\sigma_z(2)|m_j,m_j>-<m_i,m_j|\sigma_z(1)\sigma_z(2)|m_i,m_j>-12 . \quad (C14)$$

The sums are easily performed to give the required result. Similarly it may be proven that for the exchange term,

$$\sum_{m_i,m_j} <m_i,m_j|S_{12}(\hat{q})(\sigma_{l1}.\sigma_{l2})|m_j,m_i> = 0 . \quad (C14)$$
APPENDIX D

EVALUATION OF SOME INTEGRAL TRANSFORMS

The $j_0$ transform of $f_c(r)$ is given by

$$f_c(q) = \int_0^\infty j_0(qr) \frac{e^{-\mu r}}{\mu r} r^2 dr .$$

This integral is easily evaluated to give

$$f_c(q) = \frac{e^{-\mu d}}{\mu q} \left[ \frac{\mu \sinqd + q \cosqd}{\mu^2 + q^2} \right] . \quad (D1)$$

The $j_2$ transform of $f_t(r)$ is

$$f_t(q) = \int_0^\infty j_2(qr) h_2(i\mu r) r^2 dr ,$$

where $h_2(i\mu r) = T_\mu(r) Y_\mu(r)$ is a spherical Honkel function of second order. This integral has been done in reference (16), and the result is

$$f_t(q) = \frac{e^{-\mu d}}{\mu q} \left[ 3 j_1(qd) \frac{(1+\mu d)}{\mu^2 d} - \frac{\mu \sinqd + q \cosqd}{\mu^2 + q^2} \right] . \quad (D2)$$

For the effective interaction, the required $j_0$ transform is

$$g_c(q) = \int_0^\infty j_0(qr) g(r) r^2 dr ,$$
\[
= \int_{\text{d}}^{\infty} j_0(qr) [c_1 Y_\mu(r) + c_2 E_\mu(r) + c_3 Y_\eta(r) + c_4 E_\eta(r)] r^2 dr .
\]

Now
\[
\int_{\text{d}}^{\infty} j_0(qr) E_\mu(r) r^2 dr = \mu d f_c(q) - \frac{e^{-\mu d}}{q} \sin qd \left( \frac{2\mu^2 f_c(q)}{\mu^2 + q^2} \right) ,
\]

and introducing the notation \( f_c^{(\mu)}(q) \) and \( f_c^{(\eta)}(q) \), \( g_c \) becomes
\[
g_c(q) = c_1 f_c^{(\mu)}(q) + c_3 f_c^{(\eta)}(q) + c_2 [\mu d f_c^{(\mu)}(q) - \mu d f_c^{(\eta)}(q)],
\]

\[
+ c_4 [\eta d f_c^{(\eta)}(q) - \eta d f_c^{(\eta)}(q)] .
\]

The \( j_2 \) transform of \( g_t(r) \) is given by
\[
g_t(q) = c_5 \int_{\text{d}}^{\infty} j_2(qr) T_\mu(r) Y_\mu(r) r^2 dr + c_2 \int_{\text{d}}^{\infty} j_2(qr) [E_\mu(r) + Y_\mu(r)] r^2 dr + c_6 \int_{\text{d}}^{\infty} j_2(qr) T_\eta(r) Y_\eta(r) r^2 dr + c_4 \int_{\text{d}}^{\infty} j_2(qr) [E_\eta(r) + Y_\eta(r)] r^2 dr .
\]
The first and third integrals are just $f_{t}^{(\mu)}(q)$ and $f_{t}^{(\eta)}(q)$, so it is only necessary to evaluate

$$\int_{d}^{R} j_{2}(qr)[E_{\mu}(r) + Y_{\mu}(r)]r^{2}dr.$$ 

This integral may be evaluated by writing $E_{\mu}(r) + Y_{\mu}(r) = -i\mu r h_{1}(i\mu r)$, and intragrating by parts. The final result is

$$j_{2}\{E_{\mu}(r) + Y_{\mu}(r)\} = e^{-\mu d} \mu^{2} j_{2}(qd) + e^{-\mu d} \mu q \frac{\sin qd}{\mu^{2} + q^{2}}$$

$$- qd \frac{\mu \cos qd - q \sin qd}{\mu^{2} + q^{2}}] + \frac{2q^{2}}{\mu^{2} + q^{2}} f_{C}^{(\mu)}(q).$$

Then

$$g_{t}(q) = c_{5} f_{t}^{(\mu)}(q) + c_{2} j_{2}\{E_{\mu}(r) + Y_{\mu}(r)\}$$

$$+ c_{6} f_{t}^{(\eta)}(q) + c_{4} j_{2}\{E_{\eta}(r) + Y_{\eta}(r)\},$$

where the values for the constants $c_{1}$ through $c_{6}$ are the same as given in equation (A10).
APPENDIX E

THE EULER FUNCTIONS $P$, $G_0$, AND $G_2$

The direct contribution to the second order energy involves an integral over the variables $k_i$ and $k_j$ which is independent of the form of the two-body interaction. This integral was first evaluated analytically by Euler (17) and the result is (18)

$$
\int \frac{dk_i}{q} \frac{dk_j}{(q+k_i-k_j)} = \frac{4\pi^2}{15} k_F^5 \frac{P(q/2k_F)}{q},
$$

where

$$
P(u) = (4+\frac{15}{2} u - 5u^3 + 3u^5) \ln(1+u) + 29u^2 - 3u^4 + (4-\frac{15}{2} u
+ 5u^3 - 3u^5) \ln(1-u) - 40u^2 \ln 2 \text{ for } u<1,
= (4-20u^2 - 20u^3 + 4u^5) \ln(1+u) + 4u^3 + 22u + (-4+20u^2 - 20u^3
+ 4u^5) \ln(u-1) + (40u^3 - 8u^5) \ln u \text{ for } u>1.
$$

It may easily be shown that

$$
\frac{\ln P(u)}{u+1} = 26-32 \ln 2.
$$

The use of this function greatly simplifies the second order calculation, for it reduces the direct contribution to a

64
single integration over \( q \).

Because of the appearance of the variable \( s \) in the exchange contribution (equation (73)), the integrations can no longer be expressed in terms of \( P \). However, the integrations appearing in the exchange contribution which are independent of the potential have been done numerically and tabulated by Sprung\(^{(13)}\). The correspondence between his generalized Euler functions, \( G_0 \) and \( G_2 \), and the integrals appearing in the exchange contribution may be seen as follows:

According to equation (73) the central exchange contribution is proportional to the following integral:

\[
\frac{\Delta E^{(2)}_{\text{ex}}}{N} (\text{central}) \propto \int \frac{dk_{i} dk_{j} dq}{q \cdot s} y(q, s) ,
\]

(E3)

where \( y(q, s) \) is a product of \( J_0 \) transforms. Introduce the following change of variables:

\[
\begin{align*}
  k_{ij} &= k_{ij}' - s_i, \\
  k_{i} &= k_{i}' - z_i, \\
  q &= z_i .
\end{align*}
\]

(E4)

The Jacobian for this transformation may be shown to be unity, so that equation (E3) becomes

\[
\frac{\Delta E^{(2)}_{\text{ex}}}{N} (\text{central}) \propto \int \frac{dk_{ij}' ds dq}{q \cdot s} y(q, s) ,
\]

(E5)

where the proportionality constant is the same as in equation
(E3). In equation (E5), the portion of the integral which is independent of \( q \) or \( s \) is

\[
\int \frac{d\Omega_q}{\cos \theta_{sq}} \frac{d\Omega_s}{\cos \theta_{sq}} \frac{dk'_i}{\cos \theta_{i'q}} = k_F^2 16\pi^2 G_0(q/k_F, s/k_F), \tag{E6}
\]

where \( G_0 \) has been tabulated by Sprung in steps of \( q/k_F = s/k_F = 0.1 \). In an exactly similar manner, the tensor exchange contribution may be expressed in terms of \( G_2 \), and so the exchange contribution is reduced to a two-dimensional integral over the variable \( q \) and \( s \).
APPENDIX F

NOTE ON THE NUMERICAL EVALUATION OF THE FIRST
AND SECOND ORDER CONTRIBUTIONS

The exact values to be taken for the parameters appearing in the potentials v and u are in some cases rather arbitrary, either because of a lack of a unique definition (as for $\mu$) or because the quantity is not well known experimentally (as for $f_N^2$). In Table II a consistent set of values for the required parameters are given, all assumed to be accurate to three significant figures.

The most difficult first order integration to perform is that for determining $<W>/N$ in the case of non-zero $d$. If $F(q)$ is replaced by $F(q)$ in equation (51), and the q integration attempted directly, the integrand will be found to oscillate, and fall off very slowly. The alternate method is to substitute for $F(q)$, and then reverse the order of the $r$ and the q integration. The q integration can be done exactly, and there remains an integral over the finite interval, 0 to $d$, involving $r$. The final result is

$$\frac{<W>}{N}(d\neq 0) = \frac{<W>}{N}(d=0) - \frac{2c}{\mu^6} \int_0^d r^2 \left( D^2 (k_F r) (a_1 Y_1 (r) + a_2 Y_2 (r)) + a_3 E_\mu (r) + a_4 E_\eta (r) \right) r^2 dr - \frac{4\pi^2 \xi^2}{2},$$

67
where

\[ a_1 = 4\pi^2 \mu^3 \left( -2 + 2(1 - \xi) \left( \mu^2 + \eta^2 \right) / \left( \mu^2 - \eta^2 \right) - (1 - \xi) \eta^2 / (\mu^2 - \eta^2) \right), \]

\[ a_2 = 4\pi^2 \eta^3 (1 - \xi) \left( -2(1 - \xi) - 2(\mu^2 + \eta^2) / (\mu^2 - \eta^2) + \mu^2 / (\mu^2 - \eta^2) \right), \]

\[ a_3 = 3\pi^2 \mu^3, \]

\[ a_4 = 3\pi^2 (1 - \xi)^2 \eta^3. \]

All the first order integrations were done by dividing the interval of integration into an arbitrary number of subdivisions (five was found to be sufficient) and applying a ten-point Gauss quadrature routine in each subdivision. The first order contribution of \( <U>/N \) was obtained using equation (60) rather than equation (55), the two results being identical provided that \( d \) is non-zero.

The evaluation of the first order contributions requires an explicit form for \( F(q) \). This may be obtained in a straightforward but tedious manner from equation (44), and the final result is

\[ F(q) = \frac{3\pi^2}{k_F^3} \left[ 2 - 3 \left( \frac{q}{2k_F} \right) + \left( \frac{q}{2k_F} \right)^3 \right] \theta(2k_F - q), \quad (F1) \]

where \( \theta(x) \) is zero for \( x < 0 \), and is unity otherwise.

Since the second order contribution involves integrals over infinite domains, a check is necessary to determine at what point the integration may be truncated. For the direct
contributions, the same method of integration as was used in the first order calculation was applied, and it was found that carrying the integration out to $q=30F^{-1}$ was sufficient to guarantee three figure accuracy, with the major contribution coming from a region near $q=2F^{-1}$.

Because of the manner in which the functions $G_0$ and $G_2$ were tabulated by Sprung, a Simpson's rule integration routine was used in the calculation of the exchange contributions. The generalized Euler functions have been tabulated only as far as $q/k_F = 5.9$, with asymptotic expansions given for larger $q$ values. The calculation of the direct contribution would indicate that $q$ values to at least $q/k_F = 10$ are important, and so the asymptotic forms were used to extend the tables. However, since these expansions have an accuracy of approximately 1%, the third figure of the exchange contributions may be inaccurate. For this reason the last digit in the exchange contributions is enclosed in brackets in Tables IV and V.
