## Best-available evidence related to the mpox outbreak

**30 August 2024**

[MHF product code: LEP 6.12]

## Appendix 1: Methodological details

We use a standard protocol for preparing living evidence profiles (LEP) to ensure that our approach to identifying research evidence is as systematic and transparent as possible in the time we were given to prepare the profile.

### Identifying research evidence

For this LEP, we searched PubMed, Scopus, Europe PNC, and SSRN for:

- 1) evidence syntheses
- 2) protocols for ongoing evidence syntheses
- 3) published single studies
- 4) pre-prints and other emerging evidence (e.g., recent data presented at conferences).

We searched PubMed using an open text search for (((Monkeypox[All Fields] OR Monkeypox\*[All Fields] OR “Monkey pox”[All Fields] OR MPXV[All Fields] OR Monkeypox[MeSH Terms] OR Monkeypox virus[MeSH Terms] OR “Variole du singe”[All Fields] OR “mpox” [All Fields] )) AND ((clade\* 1) OR (“clade\* I”) OR (“I clade”))) OR (“Congo Basin clade” OR (“Central Africa clade”) OR (“CA clade”)). We searched Scopus using an open text for: ( TITLE-ABS-KEY ( ( Monkeypox OR “Monkey pox” OR “monkey orthodox” OR simian OR “Simian pox” OR “simian orthodox” OR mpv OR “Monkeypox virus” OR “ovariole du singe” OR “mpox” OR “orthodoxvirose simienne” OR “ovariole simienne” ) ) AND ALL ( “clade 1” ) ). We searched EuropePMC using an open text search for ((Title:(Monkeypox) OR Title:(“Monkey pox”) OR Title:(“Monkey orthopox”) OR Title:(Simianpox) OR Title:(“Simian pox”) OR Title:(“Simian orthopox”) OR Title:(MPXV) OR Title:(“Variole du singe”) OR Title:(“orthopoxvirose simienne”) OR Title:(“Variole simienne”) OR Title:(“mpox”) OR Abstract:(Monkeypox) OR Abstract:(“Monkey pox”) OR Abstract:(“Monkey orthopox”) OR Abstract:(Simianpox) OR Abstract:(“Simian pox”) OR Abstract:(“Simian orthopox”) OR Abstract:(MPXV) OR Abstract:(“Variole du singe”) OR Abstract:(“orthopoxvirose simienne”) OR Abstract:(“Variole simienne”) OR Abstract:(“mpox”)) AND (SRC:PPR)) AND ((clade 1) OR (“clade I”)). Finally, we searched SSRN using a key word search for “Monkeypox” or “Simianpox.” We also pulled evidence documents that specifically addressed clade I from two previously conducted living evidence profiles on mpox, last updated in 2022 ([1](#); [2](#)).

Evidence documents from the systematic searches were uploaded into Covidence (a software to support conducting evidence syntheses), where staff undertook title and abstract screening followed by full-text review. Documents were screened by a single reviewer. Any questions regarding inclusion or exclusion were settled by the lead author. The team uses a dedicated virtual channel to discuss and iteratively refine inclusion/exclusion criteria throughout the process, which provides a running list of considerations that all members can consult during the first stages of assessment. From the systematic searches, we screened 224 evidence syntheses and single studies (including 13 duplicates), of which 132

went to full-text review. There were 108 documents excluded following a full-text review because they did not provide findings directly relevant to clade I, they were descriptive articles that did not contain methods sections, or they were modelling studies. In addition, we hand searched the documents included in the two previous living evidence profiles and included six documents. In total, we included 30 evidence documents including seven evidence syntheses and 23 primary studies.

During this process we include published, pre-print, and grey literature. We do not exclude documents based on the language of a document. However, we are not able to extract key findings from documents that are written in languages other than Chinese, English, French, Portuguese, or Spanish. We provide any documents that do not have content available in these languages in an appendix containing documents excluded at the final stages of reviewing. We excluded documents that did not directly address the research questions and the relevant organizing framework.

## **Assessing relevance and quality of evidence**

We assess the relevance of each included evidence document as being of high, moderate, or low relevance to the question.

Two reviewers independently appraise the methodological quality of evidence syntheses that are deemed to be highly relevant using the first version of the [AMSTAR](#) tool. Two reviewers independently appraise each synthesis, and disagreements are resolved by consensus with a third reviewer if needed. AMSTAR rates overall methodological quality on a scale of 0 to 11, where 11/11 represents a review of the highest quality. High-quality evidence syntheses are those with scores of eight or higher out of a possible 11, medium-quality evidence syntheses are those with scores between four and seven, and low-quality evidence syntheses are those with scores less than four. It is important to note that the AMSTAR tool was developed to assess evidence syntheses focused on clinical interventions, so not all criteria apply to those pertaining to health-system arrangements or implementation strategies. Furthermore, we apply the AMSTAR criteria to evidence syntheses addressing all types of questions, not just those addressing questions about effectiveness, and some of these evidence syntheses addressing other types of questions are syntheses of qualitative studies. While AMSTAR does not account for some of the key attributes of syntheses of qualitative studies, such as whether and how citizens and subject-matter experts were involved, researchers' competency, and how reflexivity was approached, it remains the best general quality-assessment tool of which we're aware. Where the denominator is not 11, an aspect of the tool was considered not relevant by the raters. In comparing ratings, it is therefore important to keep both parts of the score (i.e., the numerator and denominator) in mind. For example, an evidence synthesis that scores 8/8 is generally of comparable quality to another scoring 11/11; both ratings are considered 'high scores.' A high score signals that readers of the evidence synthesis can have a high level of confidence in its findings. A low score, on the other hand, does not mean that the evidence synthesis should be discarded, merely that less confidence can be placed in its findings and that it needs to be examined closely to identify its limitations. (Lewin S, Oxman AD, Lavis JN, Fretheim A. SUPPORT Tools for evidence-informed health Policymaking (STP): 8. Deciding how much confidence to place in a systematic review. *Health Research Policy and Systems* 2009; 7 (Suppl1): S8.)

## **Preparing the profile**

Each included document is cited in the reference list at the end of the LEP. For all included guidelines, evidence syntheses, and single studies (when included), we prepare a small number of bullet points that provide a summary of the key findings, which are used to summarize key messages in the text. Protocols and titles/questions have their titles hyperlinked, given that findings are not yet available.

We then draft a summary that highlights the key findings from all highly relevant documents (alongside their date of last search and methodological quality).

Upon completion, the LEP is sent to the subject matter expert for review.

## Appendix 2: Overview of identified evidence syntheses and single studies by organizing framework domains

	Total	Biology	Epidemiology	Prevention and control	Diagnosis	Clinical presentation	Prognosis	Treatment
Total	<b>30</b>	<b>23</b>	<b>19</b>	<b>8</b>	<b>8</b>	<b>3</b>	<b>9</b>	<b>2</b>
